Eine (1:2) verkleinerte Abbildung der Dunkelwolken auf Blatt 18 des Roß-Atlas (α = 324°0; δ = 50°2) ohne Sterne.  
Durch die gestrichelten Kreise sind mit ihrer Unsicherheit die Lagen der Radiosterne  
dieses Gebietes der Milchstraße angedeutet.

## I. Einleitung

Dem vorliegenden Katalog der Dunkelwolken (DW) liegen die Atlanten der Milchstraße von Roß<sup>1</sup> und von Lick<sup>2</sup> zugrunde. Sie enthalten im Gegensatz zum neuesten Palomar-Atlas die positiven Abzüge von Milchstraßenaufnahmen und eignen sich deshalb wesentlich besser zur Auffindung und zur Ortsbestimmung von DW als die negativen Abzüge des Palomar-Atlases, weil die Schwerpunkte der Schwärzungen der DW mit oft unscharfen Rändern deutlicher erkennbar sind als die Lücken des hellen Sternuntergrundes des Palomar-Atlases. Aus demselben Grunde sind die Umrisse und die Helligkeit leuchtender Objekte, wie der planetarische Nebel im Palomar-Atlas, viel leichter als in den genannten Atlanten zu erkennen und zu messen. Die Schwärzungen der DW in diesen konnten als rohes Maß für die Absorption des Lichts benutzt werden, nachdem eine empirische Beziehung zwischen der geschätzten Schwärzung und der aus Sternzählungen innerhalb und außerhalb der DW ermittelten Absorption abgeleitet war. Ein wesentlicher Nachteil der benutzten Atlanten gegenüber dem Palomar-Atlas ist der kleinere Maßstab und die viel geringere Reichweite (17 Gr. Kl.). Aus Sternzählungen innerhalb und außerhalb der DW wird man wesentlich tiefere Regionen der Milchstraße auf den Palomar-Blättern erreichen, als es bei Benutzung der Roß- und Lick-Atlanten möglich war, und vielleicht auch bis zu kleineren Dimensionen der DW vordringen.

Die kleinsten DW des Kataloges haben Durchmesser von 2'. Es wurden nur solche DW in den Katalog aufgenommen, die mindestens auf zwei Blättern desselben oder beider Atlanten, die ganz unabhängig voneinander vermessen wurden, eindeutig feststellbar waren. Die Auswahl ist in bezug auf die kleinsten DW bei weitem nicht vollständig. Glücklicherweise ist sowohl die Grenzgröße der Sterne der beiden Atlanten praktisch dieselbe und auch der Maßstab nahezu identisch (1 mm = 3'. 8 — 4'. 0), so daß die Identifizierung sehr einfach war.

## II. Die Koordinaten

Es wurde großes Gewicht auf die Festlegung der Örter und die Form der DW gelegt. Das geschah in folgender Weise. Zunächst wurden durchsichtige Cellophanblätter auf jede Karte der Atlanten geheftet und bei starker rückseitiger Durchleuchtung auf einem dazu konstruierten Meßapparat der Schwerpunkt der Schwärzung und die Form der DW auf die Cellophanblätter durchgezeichnet. Diese wurden dann auf Millimeterpapier aufgespannt und der Schwerpunkt auf dieses übertragen, sowie der Flächeninhalt jeder DW in qmm abgelesen. Gleichzeitig wurden auch vier bis fünf Örter von Vergleichssternen mit bekannten

---

<sup>1</sup> Ross. F. E. Atlas of the Northern Milky Way. Chicago 1934-6.

<sup>2</sup> Lick, Publications, Band 11-1913 E. E. Barnard (Photographs of Milky Way and comets).

äquatorialen Koordinaten auf das Cellophanblatt und dann auf das mm-Papier übertragen. Mit ihrer Hilfe wurden dann aus den linearen, vermessenen Koordinaten nach der üblichen Turner'schen Methode die Plattenkonstanten für jedes vermessene Blatt berechnet. Diese Konstanten finden sich für alle vermessenen Blätter am Schluß der Arbeit. Aus ihnen sind dann die Koordinaten  $\alpha_{1950}$ ,  $\delta_{1950}$  fünfstellig mit der Genauigkeit von  $0.^1$  berechnet. Die aus den Einzelblättern abgeleiteten Koordinaten sind im Katalog einzeln angeführt. Bei dem errechneten Maßstabe jedes Blattes ergaben sich aus dem Flächeninhalt der DW in mm dann auch die Flächeninhalte in  $\square'$ . Auch diese sind im Katalog für jedes Blatt einzeln als Fläche eingeführt.

Der mittlere Fehler des Mittels der Örter  $\varepsilon_\alpha$ ,  $\varepsilon_\delta$  und der Flächen  $\varepsilon_f'$ , ist abhängig von der Größe der DW in der folgenden Tabelle angegeben. Er ist aus den Abweichungen von 2–5 Einzelwerten abgeleitet. Zwischen den Einzelwerten derselben DW aus 2 bis 5 verschiede-

Tabelle 1  
Mittlere Fehler in  $\alpha$ ,  $\delta$  und  $f'$

| Für DW                    | $\varepsilon_\alpha$ | $\varepsilon_\delta$ | $\varepsilon_f'$    |
|---------------------------|----------------------|----------------------|---------------------|
| mit<br>$f' < 30 \square'$ | $\pm 1.^3$           | $\pm 1.^2$           | $\pm 2.0 \square'$  |
| $30 < f' < 100 \square'$  | $\pm 1.^4$           | $\pm 2.^0$           | $\pm 5.4 \square'$  |
| $f' > 100 \square'$       | $\pm 1.^5$           | $\pm 1.^2$           | $\pm 10.6 \square'$ |

nen Blättern der zwei benutzten Atlanten ergaben sich systematische Unterschiede der einzelnen Blätter. Ihre Ursachen waren im wesentlichen kleine Unterschiede in der Schätzung der Schwerpunkte der DW und Fehler in der Übertragung der Örter vom Cellophan- auf das mm-Blatt. Diese systematischen Unterschiede konnten aus 20 bis 50 gemeinsamen DW gegen die Örter der Roß-Blätter abgeleitet werden. An die Örter aus den Lick-Blättern wurden systematische Korrekturen auf die Örter der Roß-Blätter angebracht, so daß die im Katalog angeführten Örter sich im wesentlichen auf die Konstanten der Roß-Blätter beziehen. Sie sind deshalb noch mit kleinen systematischen Fehlern der Roß-Blätter behaftet.

### III. Die Flächen der DW

Die Flächeninhalte ergaben sich bei den ganz unabhängigen Vermessungen auf den Roß- und Lickblättern manchmal bis zu 20% verschieden. Auch hier wurden für die Lick-Blätter Korrektionsfaktoren angebracht und so die Maße auf Flächen des Roß-Atlases reduziert. Auch nach diesen Reduktionen erreichen die Abweichungen der Flächen auf den verschiedenen Blättern von ihrem Mittel in Einzelfällen 20–30%, was bei den oft unscharfen und verwaschenen Grenzen verständlich ist.

### IV. Die Form der DW

Eine gewisse Unsicherheit haben auch die Umrisse der DW auf den verschiedenen Blättern, die unabhängig voneinander auf den durchsichtigen Cellophanblättern eingezeichnet

wurden. Im Katalog sind folgende Abkürzungen für die öfter auftretenden Formtypen eingeführt worden (Spalte 6).

|              |           |
|--------------|-----------|
| rund         | rd.       |
| länglich     | lgl.      |
| elliptisch   | ell.      |
| dreieckig    | $\Delta$  |
| viereckig    | $\square$ |
| unregelmäßig | urglm.    |

Manchmal ist die Formencharakteristik ungekürzt angeführt. Bestand über die Form von DW zwischen Roß- und Lickblättern ein wesentlicher Unterschied, so wurde diejenige des Roßblattes angeführt. Auch die Richtung der größten Ausdehnung der DW ist nach dem Kompaß in 16 Stufen (S, SSW, SW, WSW, W usw.) gekennzeichnet.

### V. Die Absorptionen $\Delta m$

wurden aus den Schwärzungen der DW in folgender Weise angenähert bestimmt. Als Grundlage diente die Anzahl der durch die DW durchscheinenden schwachen Sterne. Zunächst wurde festgestellt, daß die Grenzgröße sowohl bei den Roß- als auch bei den Lickblättern bei  $17^{\text{m}0} \pm 0^{\text{m}5}$  liegt. Eine Auszählung der Sternzahlen für alle Wolken des Kataloges wäre eine ungeheuere Arbeit gewesen, die zu bewältigen mir nicht möglich war. Deshalb wurde folgendes vereinfachtes Verfahren angewandt. Für jedes Blatt wurden 10 bis 30 gut definierte DW ausgewählt und für jede von ihnen die Zahl der schwächeren Sterne, die sicher Hintergrundsterne waren, sowohl innerhalb der Umgrenzung der DW als auch außerhalb derselben gezählt. Dazu wurde das durchsichtige Blatt mit der eingezeichneten Umgrenzung auf die passend gewählte Umgebung der DW verschoben. Dann wurden für jedes Blatt und jede DW des Roß- und des Lick-Atlases Verhältniszahlen der schwächeren Sterne innerhalb und außerhalb der DW berechnet und nebenbei auch Schätzungen ihrer Schwärzungen in einer 10stufigen Skala  $0,0, 0,5, 1,0, 1,5 \dots$  usw. bis 4,5 gemacht. Dann wurden für jedes Blatt der Atlanten die Beziehung der geschätzten Schwärzung zu den Verhältniszahlen innerhalb und außerhalb der DW  $\frac{N_i}{N_a}$  gebildet. Diese Tabellen zeig-

ten aber keine gesicherten Unterschiede zwischen den Blättern derselben Atlanten – ein Beweis für die Gleichartigkeit der Aufnahmen und Reproduktionen aller Blätter derselben Atlanten. Sie wurden deshalb für jeden Atlas zu einer mittleren Tabelle zusammengefaßt.

Tabelle 2

| Geschätzte<br>Schwärzungen | $\frac{N_i}{N_a}$ Roß | $\frac{N_i}{N_a}$ Lick |
|----------------------------|-----------------------|------------------------|
| 1.5                        | 0.31                  | 0.30                   |
| 2.0                        | 0.41                  | 0.40                   |
| 2.5                        | 0.59                  | 0.52                   |
| 3.0                        | 0.67                  | 0.64                   |
| 3.5                        | 0.74                  | 0.70                   |
| 4.0                        | 0.81                  | 0.80                   |
| 4.5                        | 0.83                  | 0.86                   |

## 8 VI. Vergleich der Helligkeitsschätzungen des Kataloges mit Helligkeitsmessungen derselben DW

Die innerhalb und außerhalb der DW gezählten Sterne lagen bei 15.<sup>mo</sup> — 17.<sup>mo</sup>. Wir entnahmen aus den van Rhin'schen Tabellen der Sternzahlen innerhalb der Milchstraße von 16.<sup>mo</sup> bis 17.<sup>mo</sup> den Wert

$$\frac{N_{m+1}}{N_m} = 2.15.$$

Dann wurde eine Kurve gezeichnet für die Beziehung

$$\frac{N_{m+k}}{N_m} = (2.15)^k$$

und für  $k = 1.0, 1.5, 2.0, -1.0, -1.5, -2.0$  und aus ihr die Absorptionswerte  $\Delta m = m_i - m_a$  ( $i$  — innerhalb,  $a$  — außerhalb der DW) nach den Werten  $\frac{N_i}{N_a}$  entnommen. Es ergab sich folgende Tabelle zur Umwandlung der Schwärzungsschätzungen in Absorptionsbeträge.

Tabelle 3  
Schätzung der Schwärzung und Absorption  $\Delta m$

| Schätzung | Roß | Lick |
|-----------|-----|------|
|           | $m$ | $m$  |
| 1.0       | 2.0 | 2.0  |
| 1.5       | 1.6 | 1.5  |
| 2.0       | 1.2 | 1.1  |
| 2.5       | 0.8 | 0.7  |
| 3.0       | 0.6 | 0.5  |
| 3.5       | 0.5 | 0.4  |
| 4.0       | 0.3 | 0.3  |
| 4.5       | 0.2 | 0.2  |

Nur der Vergleich der aus verschiedenen Lick- und Roßblätter auf diese Weise erhaltenen Absorptionsbeträge  $\Delta m$  derselben DW kann über ihre Genauigkeit ein Urteil ergeben. Es wäre sonst überhaupt unmöglich, den Einfluß der Platten- und Reproduktionsfehler abzuschätzen. Der Vergleich der Einzelwerte der  $\Delta m$  unseres Kataloges zeigt, daß die Mittelwerte aus 2—5 Blättern keine größeren Fehler als von 0.2  $m$  aufweisen.

## VI. Vergleich der Helligkeitsschätzungen des Kataloges mit Helligkeitsmessungen derselben DW

Genaue Absorptionsbestimmungen liegen vor für größere Gebiete der Milchstraße. Für die kleinen DW unseres Kataloges dagegen sind solche Bestimmungen, die sich zum Vergleich mit den Werten unseres Kataloges eignen, nur sehr spärlich vorhanden.

Eine genaue Ausmessung der Helligkeitsverteilung in einer kleinen DW im Schützen hat R. Kühn<sup>1</sup> durchgeführt. In meiner Arbeit:<sup>2</sup> Die Absorption und die Dichte in 31 Dunkelwolken der südl. Milchstraße, finden sich auch sieben DW dieses Kataloges.

<sup>1</sup> Forschungsberichte der Kommission Observatorium Wendelstein, Nr. 13 Rudi Kühn. Die Bestimmung der Absorption in einer kleinen DW (1956).

<sup>2</sup> Abhandlungen der Bayerischen Akademie der Wissenschaften, Neue Folge Heft 56 (1949).

In der ersten Arbeit ist die mittlere Absorption der sehr kleinen dreifachen DW mit Hilfe aufkopierter Schwärzungsmarken sorgfältig bestimmt, in der zweiten durch Vergleich der Sternzahlen innerhalb und außerhalb der DW. Der Vergleich ergibt folgende Werte  $\Delta m$   $\Delta m_1$ , wo der erste die Absorption unseres Kataloges, der zweite den oben genannten Quellen entnommen ist.

Tabelle 4

| Nr. des Kataloges | $\Delta m$ | $\Delta m_1$ |
|-------------------|------------|--------------|
| 733               | 1.10       | 1.00         |
| 742               | 0.55       | 0.51         |
| 762               | 0.45       | 0.56         |
| 761               | 0.55       | 0.56         |
| 780               | 0.45       | 0.56         |
| 811               | 0.37       | 0.42         |
| 815               | 0.53       | 0.42         |
| 816               | 0.60       | 0.42         |

Da die zweite der genannten Arbeiten sich nur auf die südliche Milchstraße bezieht, ist die Zahl der möglichen Vergleiche nur sehr gering. Die obige Tabelle zeigt keine systematischen Unterschiede innerhalb der Absorptionswerte von  $0.^m4$  —  $1.^m1$  und bestätigt auch die abgeschätzte Genauigkeit.

Ein Vergleich derselben mit den Helligkeiten der Photographischen Photometrie der nördlichen Milchstraße von A. Pannekoek<sup>1</sup> ist nicht möglich, weil die extrafokalen Bilder der Aufnahmen von M. Wolf mit Durchmessern von  $0.^{\circ}6$  bis  $0.^{\circ}8$  die Durchmesser unserer DW in den allermeisten Fällen weit überschreiten, so daß diese mit ihrer Umgebung verschmiert auf den Wolf'schen Platten erscheinen.

## VII. Die Beziehung zwischen der Fläche und der Absorption der DW

Die erhaltenen Werte der DW wurden nach der galaktischen Länge in 6 Gruppen eingeteilt und jede dieser Gruppen in sechs Unterabschnitte nach dem Flächeninhalt der DW. So entstand die folgende Tabelle.

Tabelle 5  
Einteilung der Absorptionen nach Fläche und galaktischer Länge ( $l$ )

| I                               |                  |        |            |                   |                   | II                              |                  |        |            |                   |                   |

| 80-100                          | 327-355          | 7      | 341        | 5.9          | 0.84         | 80-100                          | 55-72            | 10     | 63         | 9.4          | 0.94         |
| > 100                           | 325-357          | 19     | 341        | 15.5         | 0.82         | > 100                           | 55-74            | 25     | 65         | 23.3         | 0.93         |
|                                 |                  | 277    | 345        | 187.5        | 0.72         |                                 |                  | 270    | 65         | 211.5        | 0.84         |

Wir betrachten zunächst die Abhängigkeit der Absorption von der Fläche der DW und stellen fest, daß nur in den Gruppen I, IV und VI ein leichtes Anwachsen der Absorption bei  $DW > 80 \square'$  bzw.  $> 100'$  festzustellen ist, bei den drei anderen Gruppen ist die Absorption unabhängig von der Größe der DW. Für alle sechs Gruppen zusammengenommen ist, wie folgende Tabelle zeigt, ein schwaches Anwachsen der Absorption mit der Fläche der DW festzustellen.

Tabelle 6

| Fläche            | $A_m$ |
|-------------------|-------|
| 0- 20 $\square'$  | 0.75  |
| 20- 40 $\square'$ | 0.78  |
| 40- 60 $\square'$ | 0.78  |
| 60- 80 $\square'$ | 0.82  |
| 80-100 $\square'$ | 0.83  |
| > 100 $\square'$  | 0.87  |

Der mittlere Fehler der Einzelwerte dieser Tabelle liegt bei  $\pm 0.04$ , so daß nur ein sehr schwacher Anstieg der Absorption mit der Fläche der DW feststellbar ist.

In der ersten Arbeit über die Absorption in 31 DW der südl. Milchstraße wurde keine zunehmende Absorption mit der Größe der DW festgestellt und daraus die mögliche Deutung dieser Erscheinung darin gesucht, daß die Tiefenausdehnung der DW unabhängig von ihrer scheinbaren Größe, ähnlich einer aufgelockerten Stratuswolkenschicht der irdischen Atmosphäre dieselbe ist. Diese Hypothese soll an dem reicheren Material unseres Kataloges geprüft werden.

Zunächst wurden aus dem ganzen Katalog, ohne Unterteilung nach galaktischer Länge, die Mittelwerte der Absorption der kleinsten DW mit Flächen von 0—10 und von 11—20  $\square'$  gebildet.

$$0-10 \square' \quad A_m = 0.71 \pm 0.01 \text{ Mittel aus } 74 \text{ DW}$$

$$11-20 \square' \quad A_m = 0.73 \pm 0.01 \text{ Mittel aus } 395 \text{ DW}$$

Dann wurden aus dem Katalog alle als „rund“ bezeichneten DW ausgewählt und auch diese in zwei Gruppen  $DW \leq 20 \text{ } \square'$  und  $\leq 10 \text{ } \square'$  eingeteilt und ihre Absorption gemittelt. Es ergab sich, wenn  $N$  die Anzahl und  $\Delta m$  den Mittelwert der Absorption bedeuten

$DW \leq 20 \text{ } \square'$

$$\Sigma \Delta m = 1071, N = 152 \quad \Delta m = 0.70 \pm 0.01$$

$DW \leq 10 \text{ } \square'$

$$\Sigma \Delta m = 176, N = 26 \quad \Delta m = 0.68 \pm 0.03.$$

Endlich wurden noch die direkt als Globulen im Katalog bezeichneten DW oder auch solche als DW „mit Kern“ bezeichneten, die also nicht notwendig eine runde Umgrenzung aufweisen, ausgewählt. Sie sind in der folgenden Tabelle mit ihrer Bezeichnung zusammengestellt.

Tabelle 7

| Nr.    | Form                             | Fläche in  |            |
|--------|----------------------------------|------------|------------|
|        |                                  | $\square'$ | $\Delta m$ |
| 681    | unrglm. mit 3 Kernen             | 17         | 0.7        |
| 689    | Rhombus mit 2 Kernen             | 13         | 0.7        |
| 693    | $\Delta$ mit Globule             | 22         | 0.5        |
| 707    | Globule                          | 16         | 0.7        |
| 715    | rund mit Kern                    | 13         | 0.6        |
| 733    | $\Delta$ mit Globule             | 17         | 1.1        |
| 744    | lgl. mit Kern                    | 15         | 0.7        |
| 754    | lgl. mit Kern                    | 10         | 0.7        |
| 757    | lgl. mit Kern                    | 13         | 0.6        |
| 758    | rd. mit Kern                     | 18         | 0.7        |
| 770    | Kreuz mit Kern im Zentrum        | 24         | 0.8        |
| 816    | lgl. mit Kern                    | 14         | 0.6        |
| 822    | $\square$ mit Globule im Zentrum | 10         | 0.6        |
| 861    | rund mit Kern                    | 15         | 0.7        |
| 1106   | rund mit Kern                    | 15         | 0.7        |
| Mittel |                                  | 15         | 0.68       |

Die Schätzung der Schwärzung bezog sich immer auf die ganze DW, den Kern inbegriffen. Die Tabelle 1 für die Beziehung von Schwärzung zur Absorption wurde dabei auch für die kleinsten DW benutzt, obgleich bei ihrer Aufstellung diese ausgeschlossen waren, da bei ihnen keine oder nur ganz wenige Hintergrundsterne sichtbar waren. Es ist nicht anzunehmen, daß dadurch ein systematischer Fehler für die Absorption in den kleinsten DW eingeführt wurde, denn die Schätzung der mittleren Schwärzung bot keinerlei Schwierigkeit.

Wir erhalten somit folgende Reihe von Werten für die mittlere Absorption, die eine sehr geringe, aber doch eindeutige Abnahme der Werte mit abnehmendem Durchmesser der DW aufweist.

|  |                 |
|--|-----------------|
| Mittlere $\Delta m$ aus allen DW                                   | $0.75 \pm 0.01$ |
| Mittlere $\Delta m$ aus 395 DW $\geq 11 \leq 21 \text{ } \square'$ | $0.73 \pm 0.01$ |
| Mittlere $\Delta m$ aus 74 DW $\leq 11 \text{ } \square'$          | $0.71 \pm 0.01$ |
| Mittlere $\Delta m$ aus 152 rd. DW $\leq 20 \text{ } \square'$     | $0.70 \pm 0.01$ |
| Mittlere $\Delta m$ aus 26 rd. DW $\leq 11 \text{ } \square'$      | $0.68 \pm 0.03$ |
| Mittlere $\Delta m$ aus 15 DW mit Kern (Globulen)                  | 0.68            |

<sup>2\*</sup>

Die von mir hier als Globulen bezeichneten, kleinen und runden DW sind, auch wenn ihr Durchmesser nur  $3'$  beträgt, noch viel zu groß, um als Urstern angesprochen zu werden. Auch bei einer Entfernung von 100 pc beträgt ihr linearer Durchmesser noch 18000 A.E.

Die wahren Globulen können nur in der Projektion auf einem hellen Untergrund (planetarischer Nebel) als dunkle Punkte von  $1-3''$  festgestellt werden. Die Messung ihrer Absorption wird mit sehr großen Schwierigkeiten verbunden sein. Immerhin ist es auffallend, daß bis zu 60fach größeren Durchmessern eher eine Abnahme als eine Zunahme der Absorption mit der Abnahme ihrer Dimension festzustellen ist. Unser Katalog enthält neben den runden noch elliptische, dreieckige und s-förmige als typische Formen der DW. Wir haben auch diese in zwei Gruppen mit Flächen  $< 20 \square'$  und  $> 20 \square'$  eingeteilt und die Mittelwerte für beide Gruppen gebildet.

Wir erhielten für

|                    | Ellipsen |                   | Kreise |                   | Dreiecke |                   | S-form |                   |
|--------------------|----------|-------------------|--------|-------------------|----------|-------------------|--------|-------------------|
|                    | N        | mittl. $\Delta m$ | N      | mittl. $\Delta m$ | N        | mittl. $\Delta m$ | N      | mittl. $\Delta m$ |
| $\leq 20 \square'$ | 28       | 0.757             | 150    | 0.702             | 48       | 0.700             |        |                   |
| $> 20 \square'$    | 109      | 0.771             | 109    | 0.781             | 86       | 0.759             | 13     | 0.693             |

$N$  bezeichnet die Anzahl der in das Mittel eingehenden DW. Für alle Formen derselben bestätigt sich die Abnahme der Absorption mit der Dimension der Wolken. Wir haben in unserer ersten Arbeit (1) keine Abhängigkeit der Absorption der vermessenen 31 DW der südlichen Milchstraße von ihrer wahren Größe feststellen können. Dabei waren ihre Entfernungen aus dem Betrage der selektiven Absorption abgeschätzt. Die scheinbaren Durchmesser unseres Kataloges bestätigen das bis auf die geringe Abnahme der Absorption bei den hier sehr viel kleineren DW. Bis auf die Abnahme der kleinsten DW ist unsere frühere Hypothese von nahezu gleicher Tiefe der DW bestätigt. Die Hypothese kann noch auf andere Weise geprüft werden. Flache Gebilde müßten eine Abhängigkeit der Absorption von dem Winkel aufweisen, unter dem die flachen Scheiben vom Sehstrahl durchstoßen werden.

## VIII. Der Einfluß des Winkels der Durchstoßung auf die Absorption der DW

Zur Prüfung der obigen Hypothese benutzen wir die Einteilung des Materials in sechs Gruppen, wie es in Tabelle 5 angegeben ist. In der Fig. I sind die Verhältnisse anschaulich dargestellt, wobei der Radius der Galaxis  $R = 9000$  pc und der Umkreis, in dem die kleinen Dunkelwolken sichtbar sind, mit  $r = 750$  pc, angenommen ist. Auch die galaktischen Längen  $l$  für die sechs Gruppen der DW sind eingetragen, und zwar ungeachtet ihrer wahren Entfernungen auf dem kleinen Kreise. Für die Gruppe I mit  $l = 105^\circ$  ist auch die Verbindungsline von I mit dem galaktischen Zentrum angegeben, dessen Länge  $326.^o$  ist. Die Längen von diesem Zentrum aus sind mit  $\lambda$  bezeichnet.

Der Winkel am galaktischen Zentrum ist mit  $\alpha$  bezeichnet und der Winkel bei I mit  $x$ . Das ist der Durchstoßungswinkel der in der Richtung der Kreisbewegung um das galakti-

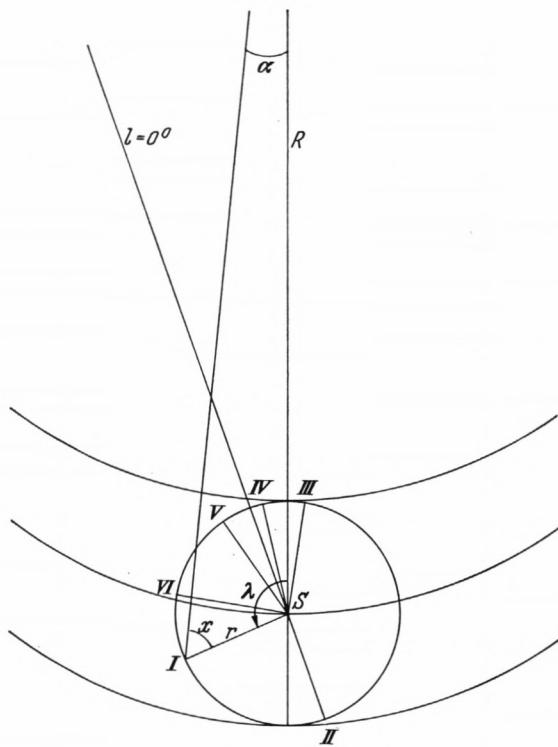

Fig. I: Die Lage der VI Wolkengruppen

sche Zentrum verlängerten, als planparallele Platten angenommenen DW. Der dritte Winkel im schmalen Dreieck zwischen dem Zentrum der Milchstraße, dem Punkte I und der Sonne sei  $x$ .

Wir haben

$$\frac{r}{R} = \frac{\sin \alpha}{\sin x}$$

$$\lambda = l + 34^\circ$$

und

$$\alpha = \pi - (\lambda + x) \text{ und}$$

$$r = R (\cos \lambda + \cotg x \sin \lambda) \quad (1)$$

$$\cotg x = \frac{r}{R} \csc \lambda - \cotg \lambda.$$

Hier ist das erste Glied wegen des kleinen Faktors  $\frac{r}{R}$  sehr klein, und die Winkel  $x$  und  $\lambda$  unterscheiden sich nur wenig, was aus folgender Tabelle, die diese Winkel und die zugehörigen, mittleren Absorptionswerte der sechs Gruppen der DW enthält, hervorgeht.

Tabelle 8

|     | $\lambda$ | $x$  | $\Delta m$ |
|-----|-----------|------|------------|
| I   | -41°      | 39°  | 0.90       |
| II  | -27°      | 26°  | 0.88       |
| III | 0°        | 0°   | 0.68       |
| IV  | 19°       | -20° | 0.72       |
| V   | 52°       | -54° | 0.81       |
| VI  | -81°      | 78°  | 0.84       |

Nach Zusammenfassung in vier Gruppen mit stetig anwachsenden Werten des Durchstoßungswinkels  $x$  tritt das Anwachsen der Absorption mit wachsendem  $x$  deutlich hervor.

Tabelle 9

|                         | $x$ | $\Delta m$ |
|-------------------------|-----|------------|
| III                     | 0°  | 0.68       |
| $\frac{1}{2}$ (IV + II) | 23° | 0.80       |
| $\frac{1}{2}$ (I + V)   | 47° | 0.86       |
| VI                      | 78° | 0.84       |

Die Abweichung bei der Gruppe VI, bei der die Gesichtslinie die Ebene streift, kann auf die grobe Vereinfachung einer planparallelen Begrenzung, bei den sehr verschiedenen Formen der DW erklärt werden.

Die DW sind demnach als flache, senkrecht zur Richtung der galaktischen Rotation abgeflachte Gebilde zu betrachten.

## IX. Die in der Rotationsrichtung verlängerte Form der DW

Beim Durchzeichnen der DW wurde neben der schematischen Charakteristik der Form auch die Richtung ihres größten Durchmessers in acht- und manchmal sechzehnstufiger Skala geschätzt, nach den Kompaßstrichen N, NNO, NO, NOO, O usw., soweit die DW nicht als rund oder so unregelmäßig begrenzt erschien, daß eine Vorzugsrichtung nicht bestimmbar war. Die Daten finden sich in Spalte 7 des Kataloges. Diese Verlängerungsrichtung ist in bezug auf die Richtung der Rotation immer zweideutig. Man kann aber annehmen, wenn eine Vorzugsrichtung überhaupt vorhanden ist, daß die zufällig in umgekehrter Richtung rotierenden DW nur einen kleinen Bruchteil in der Gesamtsumme aller in einer bestimmten Richtung verlängerten DW ausmachen. Außerdem muß man erwarten, daß die Anzahl der ohne Vorzugsrichtung, d. h. „runden“ DW in den galaktischen Längen  $l = 60^\circ$  oder  $l = 150^\circ$  gegenüber der Anzahl in anderen galaktischen Längen überwiegen muß. Die DW des Kataloges wurden in sechs Gruppen mit wachsender galaktischer Länge eingeteilt, ohne Rücksicht auf ihre galaktische Breite, und für jede Gruppe die mittlere Deklination gebildet.

Wir bilden das rechtwinkelige sphärische Dreieck zwischen dem Ort der DW (S) auf der Galaxis, dem Pol des Aequators (P) und dem Ort (G) auf der Galaxis mit der Länge

$\ell = 90^\circ$ . Die Neigung der Galaxis zu den Deklinationskreisen  $\delta$  bezeichnen wir mit  $A$ . Der Winkel PSG ist dann  $90^\circ - A$ , die Seiten  $SP = 90^\circ - \delta$ ,  $PG = 28^\circ$ . Es ergibt sich dann

$$\cos A = \frac{\sin 28}{\cos \delta}$$

für den theoretischen Neigungswinkel der Galaxis zur O-W-Richtung.

Andererseits kann dieser Winkel aus der Anzahl der DW, die in der NS-Richtung verlängert sind, zu der Anzahl der in OW-Richtung verlängerten gefunden werden, wenn man sich diese Anzahlen als Vektoren in der NS- bzw. OW-Richtung dargestellt denkt. Es müßte dann, wenn diese Anzahlen durch  $N_{n-s}$  und  $N_{o-w}$  bezeichnet werden,

$$\frac{N_{n-s}}{N_{o-w}} = \tan A.$$

Wenn eine Verlängerung der DW in der Ebene der Galaxis vorhanden ist, müßten der theoretische und der Beobachtungswert von  $A$  identisch sein, soweit die DW alle in der galaktischen Ebene liegen würden. Nicht einmal die Hauptebene der verstreut um die Galaxis liegenden DW fällt mit ihr zusammen, wie wir in einem späteren Kapitel sehen werden. Außerdem gibt es bedeutende lokale Abweichungen einzelner DW von der galaktischen Hauptebene. Es sind deshalb bedeutende Unterschiede des theoretischen und des praktischen Wertes von  $A$  zu erwarten.

In der Tabelle 10 ist die Anzahl der DW mit den Bezeichnungen O-W und N-S in den Spalten 2 und 3, sowie ihr Verhältnis unter  $\tan A$  in Spalte 4 eingetragen. Spalte 5 enthält die Deklination  $\delta$  für den Mittelwert von sechs Gruppen der DW. Diese sechs Gruppen entsprechen der Einteilung der Tabelle 5 und der Fig. I.

Tabelle 10

|     | O-W | N-S | $\frac{N-S}{O-W}$  | $A$  | $\delta$ | Nr. | $\frac{Nr.}{N_{o-w}}$ | $\ell$ |
|-----|-----|-----|--------------------|------|----------|-----|-----------------------|--------|
| I   | 17  | 20  | 1.176<br>= Tg 49°6 | 42°8 | + 50.2   | 31  | 1.82                  | 105    |
| II  | 38  | 50  | 1.316<br>= Tg 52°8 | 61°8 | + 5.5    | 33  | 0.87                  | 174    |
| III | 114 | 133 | 1.167<br>= Tg 49°4 | 58°0 | - 27.5   | 111 | 0.97                  | 326    |
| IV  | 37  | 87  | 2.351<br>= Tg 67°0 | 62°0 | - 2.0    | 35  | 0.95                  | 345    |

| VI  | 25  | 44  | 1.762<br>= Tg 60°4 | 39°5 | + 52.5   | 34  | 1.36                  | 65     |

Nur die Mittelwerte der Neigungswinkel der Galaxis zu den Deklinationskreisen ( $A$ ) und der Vorzugsrichtung der DW stimmen recht gut überein. Die Einzelwerte zeigen die erwarteten bedeutenden Abweichungen.

Bilden wir aber das Verhältnis  $N_r$  der rund erscheinenden DW zu den in der OW-Richtung ausgerichteten (Spalte 8), so zeigt sich deutlich, daß dieses Verhältnis der erwarteten Ausrichtung der DW längs der Galaxis entspricht. Ein Blick auf die Figur I zeigt, daß die

Gruppen I und VI nahezu parallel zur Rotationsrichtung der Milchstraße liegen, dagegen die Gruppen II, III, IV und V nahezu senkrecht für den Beobachter in S. Die Verhältnisse  $\frac{N_r}{N_{o-w}}$  sind im Mittel 1.6 und 0.9, womit die Ausrichtung der DW in der Rotationsrichtung der Milchstraße bestätigt ist.

## X. Die Frequenz der DW in dem Milchstraßengürtel

Die im Katalog angeführten galaktischen Koordinaten der DW (Spalte 8) sind den Tabellen von J. Ohlsson, Annals of the Observatory of Lund, Nr. 3 (1932) entnommen, denen die Koordinaten  $A = 190^\circ$ ,  $D = +28^\circ$ , des Pols der Galaxis zugrunde liegen.

Wenn auch die Auswahl der DW bis zu einem gewissen Grade willkürlich und sicher nicht vollständig war, so kann ihre Auswahl trotzdem als homogen angesehen werden, weil sie praktisch von einem Beobachter (dem Verfasser und seiner Mitarbeiterin, Frau E. Brockmann unter seiner Kontrolle) ausgeführt wurde. Wie schon erwähnt, wurden nur solche DW in den Katalog aufgenommen, die sich auf mindestens zwei Blättern der benutzten Atlanten in gleicher Form identifizieren ließen. Zur Bestimmung der Verteilung der DW des Kataloges wurde folgendes Verfahren angewandt.

Zunächst wurde das gesamte Material der DW in Streifen von  $10^\circ$  galaktischer Länge eingeteilt und die Anzahl der DW für jeden Grad Länge und Breite ausgezählt. Sodann wurde die mittlere Breite für jede 10-Grad-Längenzone berechnet. So ergab sich folgende Tabelle der mittleren Breiten ( $b$ ) für 23 Längenzonen. Dabei fehlen die Zonen zwischen  $l = 214^\circ$  bis  $l = 311^\circ$ , da die verwendeten Atlanten nur bis  $l = 311^\circ$  und zur südlichen Deklination  $b = -40^\circ$  reichen.

Tabelle 11

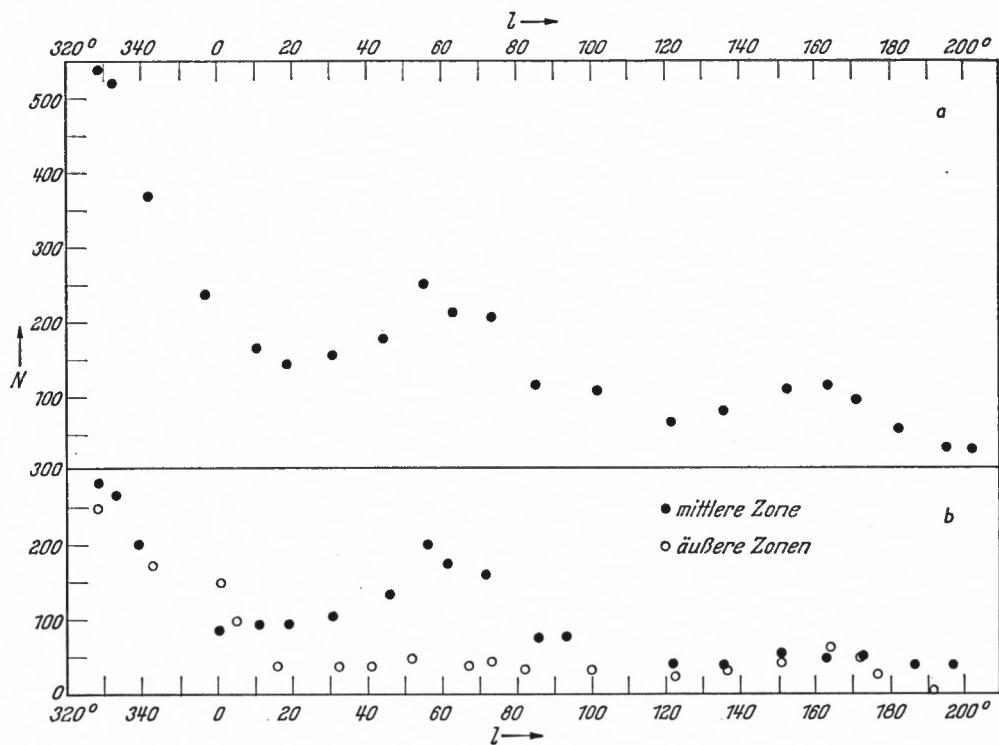

| Nr. | mittlere Länge | mittlere Breite | Anzahl |
|-----|----------------|-----------------|--------|
| 1   | $315^\circ$    | $+2^\circ 17$   | 62     |
| 2   | $325^\circ$    | $-2.41$         | 238    |
| 3   | $335^\circ$    | $+1.23$         | 240    |
| 4   | $345^\circ$    | $-3.24$         | 44     |
| 5   | $355^\circ$    | $-5.21$         | 84     |
| 6   | $0^\circ$      | $-4.21$         | 54     |
| 7   | $10^\circ$     | $-1.55$         | 57     |
| 8   | $20^\circ$     | $-1.45$         | 56     |
| 9   | $30^\circ$     | $-2.26$         | 34     |
| 10  | $40^\circ$     | $+0.61$         | 40     |
| 11  | $55^\circ$     | $-1.42$         | 76     |
| 12  | $65^\circ$     | $-0.23$         | 112    |
| 13  | $75^\circ$     | $+3.91$         | 75     |
| 14  | $85^\circ$     | $-2.59$         | 69     |
| 15  | $100^\circ$    | $-3.32$         | 19     |
| 16  | $125^\circ$    | $-5.37$         | 20     |
| 17  | $135^\circ$    | $+2.84$         | 28     |
| 18  | $145^\circ$    | $-4.64$         | 30     |
| 19  | $165^\circ$    | $-2.64$         | 53     |
| 20  | $175^\circ$    | $-6.00$         | 33     |
| 21  | $185^\circ$    | $+3.13$         | 11     |
| 22  | $195^\circ$    | $-0.66$         | 14     |
| 23  | $207^\circ$    | $+0.96$         | 18     |

Um die starken Schwankungen in den Werten der Breiten etwas zu glätten, wurden übergreifende Dreiermittel berechnet. Dabei wurden die Gewichte, entsprechend der Anzahl der DW, sowohl für die Breiten als auch die mittleren Längen angesetzt. So entstand folgende Tabelle 12 die nur 21 Werte enthält.

In dieser Tabelle ist in den Spalten V bis X das Material noch aufgespalten: in die zentrale Zone, welche die Breiten zwischen  $l = +4^\circ$  und  $b = -4^\circ$  enthält und die äußeren Zonen für die Breiten  $4^\circ < b < -4^\circ$ . Die Zahlen dieser Tabelle 12 sind auch in den Figuren II a und II b dargestellt, in denen die Abszissen die Längen, die Ordinaten die Anzahl der DW in den  $10^\circ$ -Längenzonen bedeuten. Wir sehen im oberen Diagramm  $\alpha$  für alle DW außer dem Maximum bei  $l = 330^\circ$ , das dem Zentrum der Galaxis entspricht, noch zwei weitere Maxima bei  $l = 60^\circ$  und  $l = 163^\circ$ , das letztere in der Nähe des Gegenpunktes zum galaktischen Zentrum. Für die mittlere Zone ist das letztere Maximum verschwunden. In den äußeren Zonen ist dagegen das Maximum bei  $l = 60^\circ$  nicht mehr feststellbar. Bei diesen Zonen ist dagegen das Maximum bei  $165^\circ$ , wenn auch sehr abgeschwächt, noch angedeutet. Die Erklärung für diese Verteilung soll in einem späteren Kapitel behandelt werden.

Tabelle 12

|    | Alle Dunkelwolken |            |        | Zentrale Zone |            |        | Äußere Zonen $4^\circ < b < -4^\circ$ |            |        |

Fig. II: Die Anzahl der DW in den Dreiermitteln der  $10^\circ$ -Zonen.

## XI. Die mittleren Breiten

Unsere Tabelle 12 enthält auch die mittleren Breiten der Dreiermittel aus übergreifenden  $10^\circ$ -Längen-Zonen. In Fig. III sind diese Breiten sowohl für alle DW (oben) als auch für die zentrale Zone dargestellt. Dabei ist die Anzahl der in die Mittelwerte eingehenden DW durch die Größe der Kreise angedeutet. Wir sehen, daß für die zentrale Breitenzone nur kleine Abweichungen von der Zentrallinie der Galaxis auftreten, die  $1.5^\circ$  nicht überschreiten. Dagegen liegt die Kurve der mittleren Breiten für alle Breitenzonen bis auf 2 Punkte ganz südlich der Galaxis und würde eine Zentrallinie bei etwa  $b = -2.5^\circ$  verlangen. Der unregelmäßige Verlauf der DW gegenüber der aus der Sterndichte abgeleiteten Zentrallinie der Milchstraße deutet darauf hin, daß sich der Zug der DW durch Überlagerung zweier oder mehrerer Arme von verschiedenener Neigung zur Zentrallinie zusammensetzt.

Wenn man die Tabelle 12 für die äußereren Breitenzonen graphisch in der Fig. III a darstellt, so findet sich auch sofort die Erklärung für den eigentümlichen Verlauf der mittleren Breiten für alle DW (obere Kurve in Fig. III). Die Fig. III a hat eine Mittellinie bei  $b = -3.5^\circ$  und deutet durch ihren ganzen Verlauf südlich der Zentrallinie der Galaxis auf die Existenz eines getrennten, südlich verlaufenden Armes der Milchstraße. In Verbindung mit der zentralen Zone der DW ergibt sich erst der eigentümliche Verlauf der Breitenkurve für alle Zonen.

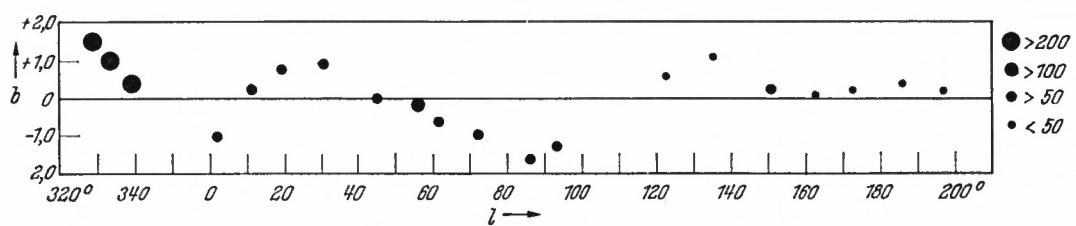

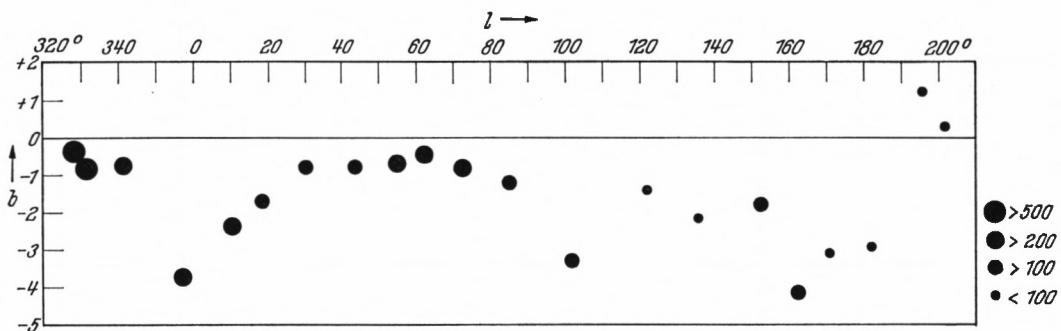

Fig. III: Obere Kurve: mittlere Breite  $b$  der DW in den  $10^\circ$ -Längszonen für alle DW

Untere Kurve: mittlere Breite  $b$  der DW in den  $10^\circ$ -Längenzonen für die mittleren Breitenzonen

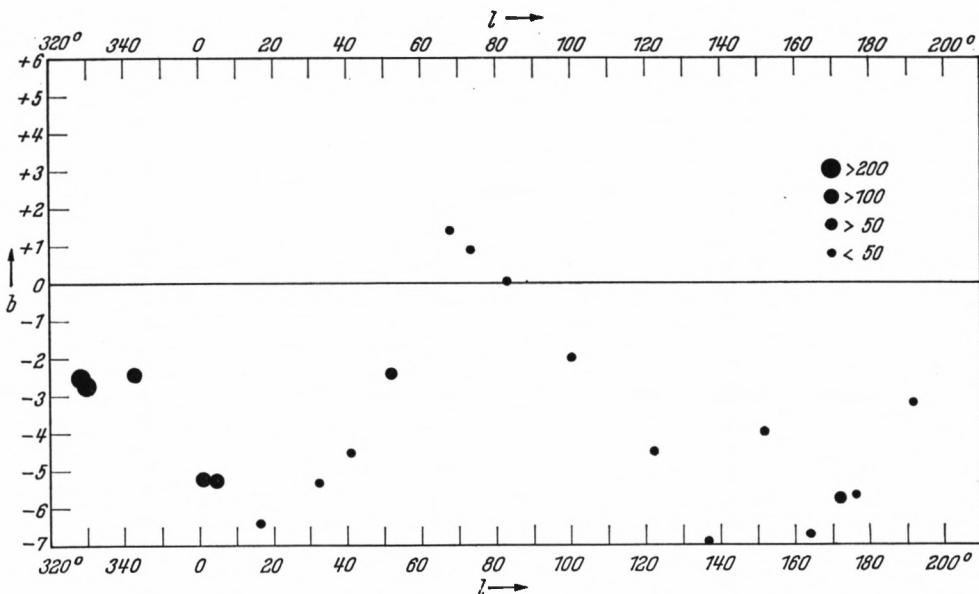

Fig. IIIa: Mittlere Breite  $b$  der DW in den  $10^\circ$ -Längenzonen für die äußeren Breitenzonen

## XII. Die Orientierung der DW gegen die Milchstraße

Wir berechnen die Lage des Poles der Zentraallinie sowohl für die Gesamtheit der DW als auch für die zentrale Zone. Dabei benutzen wir für die Ausgangswerte der aequatorialen Koordinaten des Poles der Milchstraße  $A_0, D_0$

$$A_0 = \delta\delta_0 - 90^\circ \quad D_0 = 90^\circ - i$$

$$\text{bei } \delta\delta_0 = 280^\circ = 18^h 40^m; i = 62^\circ,$$

die den Ohlson'schen Tafeln zugrunde liegen und die Formel von P. P. Parenago<sup>1</sup>

$$b = -\Delta R + 0.883 \cos l \Delta \delta - \sin l \Delta i$$

wo  $-\Delta R$  die Breite des kleinen Kreises der Milchstraße ist. Die Tabelle 12 enthält 21 Mittelwerte von  $l$  und  $b$  und die Anzahlen der DW, die in diese Mittelwerte eingehen.

Wir erhielten für die Gesamtheit der DW aus 21 Werten

|                        | $\Delta R$ | $\Delta \delta$ | $\Delta i$ |
|------------------------|------------|-----------------|------------|
| bei gleichem Gewicht   | + 1°.4     | + 0°.4          | + 0°.3     |
| bei ungleichem Gewicht | + 1. 5     | + 0 .1          | + 0 .5     |

Dagegen erhielt ich für die zentrale Zone aus 20 Mittelwerten

|                        |        |        |          |
|------------------------|--------|--------|----------|
| bei gleichem Gewicht   | - 0°.4 | + 0°.9 | + 0°.05  |
| bei ungleichem Gewicht | - 0 .5 | + 1 .1 | + 0 .07. |

Die Gesamtheit der DW gibt somit als Zentraallinie einen kleinen Kreis, der um 1°.5 südlich von der Ohlson'schen Galaxis liegt, was aus den Figuren auch abzulesen wäre, wenn in ihnen die südliche Abweichung auch größer erscheint.

Es liegt die Vermutung nahe, daß die DW der äußeren Zonen, die die starke Abweichung der Mittellinie der DW verursachen, von einem oder mehreren Armen der Milchstraßenspirale, die eine Neigung gegen die Hauptebene besitzen, verursacht sind. Freilich ist die beobachtete Anzahl der DW abhängig von der Dichte des Sternhintergrundes und gibt kein objektives Maß ihrer wirklichen Verteilung, Dessen ungeachtet soll der Versuch gemacht werden, die Deutung der Verteilung der DW auf verschiedenen geneigte Arme zurückzuführen.

Die Differentialformel

$$\frac{di}{\sin l} = -db$$

---

<sup>1</sup> P. P. Parenago, Astronomical Journal of Soviet Union XIII, 4 (1937).

gibt die Abhängigkeit der Breitenkorrektion  $\Delta b$  gegen die Ebene der Galaxis eines zu dieser um  $\Delta i$  geneigten Kreises und wurde versuchsweise auf die Breiten der nördlichen und südlichen Zonen der Tabelle 12 angewandt.

Es zeigte sich, daß sich bei den um  $180^\circ$  abweichenden Längen die Korrekturen in Breite nahezu gleich, aber von umgekehrten Zeichen sind, z. B. bei  $l = 148^\circ 8$  nördlich die Korrektion  $+5^\circ 6$  bei  $325^\circ 8$  südlich die Korrektion  $-6^\circ 3$ .

Tabelle 13

| Nördliche Zone |            |            |                        | Südliche Zone |            |            |                        |
|----------------|------------|------------|------------------------|---------------|------------|------------|------------------------|
| mittl. $l$     | mittl. $b$ | $\Delta i$ | gewichtetes $\Delta i$ | mittl. $l$    | mittl. $b$ | $\Delta i$ | gewichtetes $\Delta i$ |
| 325° 9         | + 6° 1     | + 11° 37   | + 11° 79               | 325° 8        | - 6° 3     | - 11° 55   | - 11° 06               |
| 148.8          | + 5.6      | - 14.28    | - 11.06                | 126.9         | - 9.1      | + 12.74    | + 14.54                |

Die Zahlen der Tabelle sind Mittel aus jeweils drei Werten, die nahezu um  $180^\circ$  in Länge voneinander abweichen. Die Werte von  $\Delta i$  sind einmal mit gleichem Gewicht, das anderemal entsprechend der Gesamtfläche der DW, die in das betreffende Mittel eingehen, angesetzt. Das Verhalten der Korrekturen entspricht zwei gegen die Galaxis geneigten Kreisen, in deren Schnittpunkt die Anhäufung der DW in der Länge  $l = 60^\circ$  möglicherweise erklärt werden kann, wobei zu berücksichtigen wäre, daß auch die Zentrallinie der DW südlich von der Ebene der Galaxis liegt.

### XIII. Die Nebenarme der DW

Für die Berechnung der Zentrallinie dieser Nebenarme der DW kann die Differentialformel von Parenago nicht benutzt werden, weil beträchtliche Abweichungen von den Ohlson'schen Koordinaten des Milchstraßenpoles zu erwarten sind. Wir wenden deshalb die Newcomb'sche Methode zur Bestimmung der galaktischen Koordinaten der Pole der Nebenarme der DW an. Die Formel lautet:

$$\cos b \cos l \cos B \cos L + \cos b \sin l \cos B \sin L + \sin b \sin B + \sin R = 0,$$

wo  $B$  und  $L$  die galaktischen Koordinaten des Poles sind.

Wir benutzen dabei eine Auswahl von 7 um ungefähr  $180^\circ$  in Länge entfernten Werten aus der nördlichen und südlichen Zone Tabelle 14, die in folgender Tabelle zusammengestellt sind. Sie enthält neben den galaktischen Koordinaten auch die nach der Formel

$$\frac{\Delta i}{\sin l} = -\Delta b$$

angenähert berechneten Korrekturen der Neigung  $\Delta i$  und die Gewichte  $p$ , die nach der Anzahl der eingehenden Einzelwerte angesetzt sind.

XIV. Die scheinbaren Flächen der DW in  $\square'$ 

| $l$   | Nördliche Zone |        |     | $p$ | $l$   | Südliche Zone |        |     | $p$ |
|-------|----------------|--------|-----|-----|-------|---------------|--------|-----|-----|
|       | $b$            | $di$   | $p$ |     |       | $b$           | $di$   | $p$ |     |
| 318°0 | +5°4           | + 8.07 | 3   |     | 105°7 | - 6°2         | + 6.44 | 0.3 |     |
| 325.2 | +6.9           | +12.09 | 1.5 |     | 127.9 | -12.0         | +15.22 | 1.5 |     |
| 334.5 | +6.0           | +13.94 | 5   |     | 147.1 | - 9.0         | +16.56 | 0.7 |     |
|       |                |        |     |     | 165.6 | -10.0         | +40.21 | 1.5 |     |

Das Ergebnis ist für die galaktischen Koordinaten des Poles dieses Armes der DW

$$L = 5^{\circ}4 \quad B = 79^{\circ}2 \quad R = -2^{\circ}7.$$

Der Arm hat somit eine beträchtliche Neigung gegen den Ohlson'schen Aequator der Milchstraße. Er trägt den starken, südlichen Abweichungen bei  $l = 160^{\circ}$  Rechnung. Der Verlauf dieses Armes der DW ist in die Figur IV eingetragen. Der Anhäufung der DW in der galaktischen Länge  $l = 60^{\circ}$  trägt der Verlauf dieses Armes nur ungenügend Rechnung, weil der Schnittpunkt mit der Galaxis bei  $l = 80^{\circ}$  liegt. Dagegen kann auch ein anderer Nebenarm der DW angenommen werden, in dem die zugrunde gelegten Daten in der folgenden Tabelle zusammengestellt sind.

| $l$   | Südliche Zone |        |     | $p$ | $l$   | Nördliche Zone |        |     | $p$ |
|-------|---------------|--------|-----|-----|-------|----------------|--------|-----|-----|
|       | $b$           | $di$   | $p$ |     |       | $b$            | $di$   | $p$ |     |
| 318°3 | -7°0          | -10°52 | 1.5 |     | 137°8 | + 5°8          | - 8.64 | 1.5 |     |
| 325.5 | -5.9          | -10.42 | 5   |     | 141.5 | + 5.0          | - 8.03 | 0.3 |     |
| 337.6 | -6.1          | -13.72 | 1.5 |     | 167.2 | + 5.8          | -26.18 | 0.3 |     |
| 344.1 | -6.3          | -23.0  | 0.7 |     | 176.3 | + 3.5          | -55.25 | 2.1 |     |
| 355.5 | -5.7          | -72.65 | 5   |     |       |                |        |     |     |

Hier ergibt die Auflösung der Newcomb'schen Gleichung

$$L = 158^{\circ}3 \quad B = 84^{\circ}7 \quad R = -0^{\circ}8.$$

Auch der Verlauf dieses hypothetischen Nebenarmes ist in Figur IV eingetragen. Er gibt als Schnittpunkt mit der Zentrallinie der Galaxis die Länge  $l = 60^{\circ}$  und würde damit der Häufung der DW in dieser galaktischen Länge (siehe Fig. II) gerecht werden.

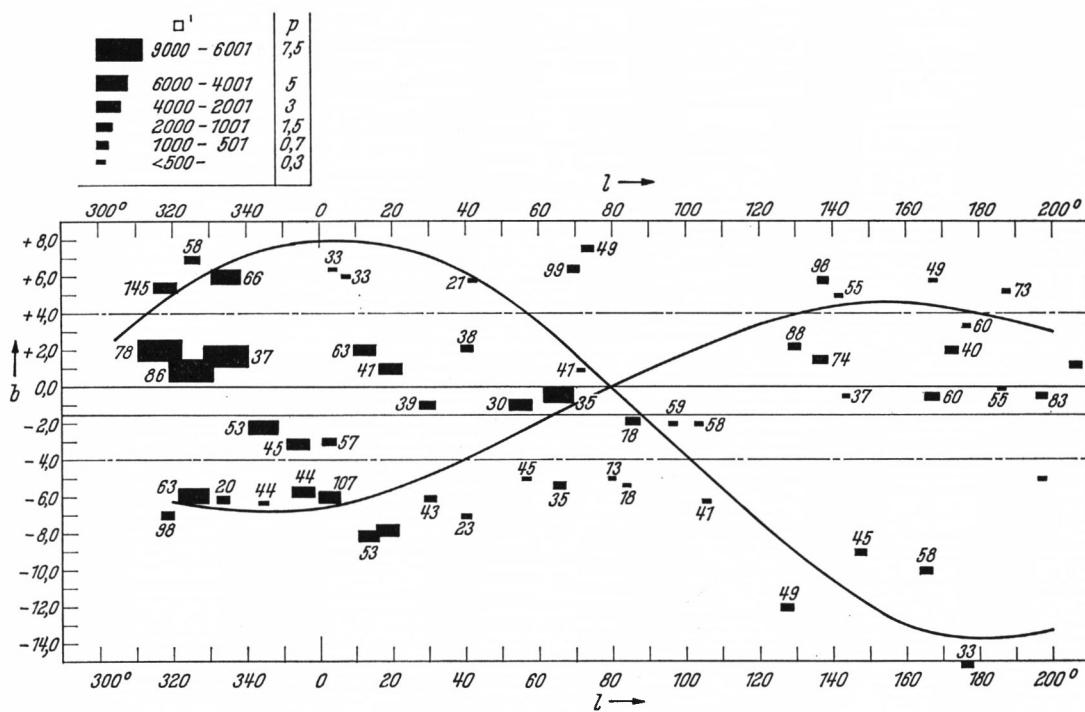

XIV. Die scheinbaren Flächen der DW in  $\square'$ 

Wir wenden uns jetzt der Frage nach den scheinbaren mittleren Flächen der DW zu.

Die folgende Tabelle enthält die aus dem Katalog entnommenen Gesamtflächen, ihre Anzahl  $N$  für die  $10^{\circ}$ -Längenzonen. Die Spalten 5 und 6 enthalten die sich aus diesen Zahlen ergebenden mittleren Flächen, und zwar in Spalte 5 für alle ( $N$ ) DW der Zone, die Spalten 7—12 bzw. 13—18 die entsprechenden Zahlen für die nördliche und die südlische Zone.

Tabelle 14  
Flächensummen in  $\square'$  für  $10^\circ$ -Längenzonen

| Zentrale Zone |      |              |     | Nördliche Zone                       |           |       |      |              |     | Südliche Zone                        |           |       |       |              |     |                                      |           |

Fig. IV: Flächensummen in  $\square'$  für  $10^\circ$ -Längenzonen

Die Verhältnisse sind auch in Fig. IV anschaulich dargestellt. Sie enthält die Gesamtflächen durch Rechtecke verschiedener Größe (Spalte 3 der Tabelle) nach den galaktischen Koordinaten eingetragen und auch durch eine, bei jedem Rechteck stehende Zahl, die durchschnittlichen Flächen der kleineren DW. Die Figur zeigt die starke Anhäufung der DW im Kern der Milchstraße ( $l = 330^\circ$ ), als Zentrallinie den Breitengrad ( $b = -1^\circ 6$ ), im übrigen aber eine große Unregelmäßigkeit in der Verteilung und den Flächen. Eine gröbere Aufteilung des Materials in acht Längenzonen von  $30^\circ$  und die Analyse der Flächeninhalte der DW wird uns noch einige Schlüsse über ihre räumliche Verteilung gestatten.

## XV. Die mittleren Radien und die Entfernungen der DW

Wir teilen das Material in acht Zonen, mit Längenintervallen von  $30^\circ$ , und bilden die Mittelwerte für die durchschnittlichen Flächen der kleineren DW (Spalten 6, 12, 18 unserer Tabelle 14), wobei wir die Anzahlen  $N$  (Spalten 4, 10, 16) berücksichtigen.

So ergibt sich die

Tabelle 15

| V    | 95.8   | —           | —                | 68         | 25               | 17         | 26               | 85         | 25               |
| VI   | 136.5  | 10          | 78               | 39         | 66               | 29         | 47               | 78         | 60               |
| VII  | 169.6  | 8           | 55               | 43         | 53               | 30         | 45               | 81         | 50               |
| VIII | 196.6  | 4           | 73               | 20         | 72               | 2          | 74               | 26         | 72               |

Die Lagen der acht Wolkengruppen sind auf Fig. V dargestellt, wobei wieder nur die Längen  $l$  berücksichtigt sind. Da nach den vorigen Abschnitten eine flache Form der

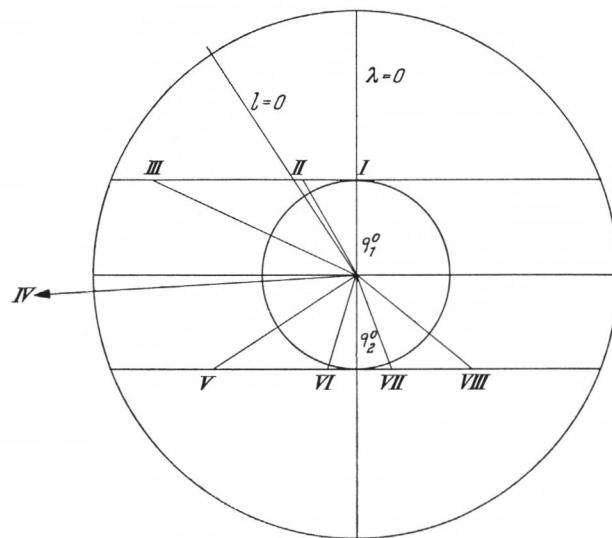

Fig. V: Die Lage der 8 Wolkengruppen bei  $q_1^0 = q_2^0 = 250$  pc

Wolken und ihre Ausrichtung längs der galaktischen Rotation nachgewiesen sind, so ist es naheliegend, sie räumlich auf konzentrischen Kreisen um das galaktische Zentrum angeordnet zu denken. Innerhalb der Sichtbarkeitsgrenze der DW von 750 pc und einem Abstande der Sonne von 9000 pc können wir die konzentrischen Kreise als parallele Gerade ansehen, die senkrecht auf der Verbindungslinie zum galaktischen Zentrum ( $\lambda = 0^\circ I = 326^\circ$ ) stehen. Wir denken uns zunächst zwei solche Wolkenzüge mit den Entfernungen  $q_1$  und  $q_2$  von der Sonne. Wir nehmen weiter an, daß die wahren Halbmesser der flachen Wolkenscheiben gleich groß sind, ihre scheinbaren Halbmesser aber von der Entfernung abhängen. Die wahren Längen vom galaktischen Zentrum aus gerechnet seien  $\lambda_i$ . Bei der Annahme zweier Wolkenzüge mit den Abständen  $q_1^0$  und  $q_2^0$  sind die wahren Abstände von der Sonne (siehe Fig. V) für die acht Wolkengruppen

$$\begin{aligned} q_i &= q_1^0 \sec \lambda_i \text{ mit } i = 1, 2, 3 \\ q_i &= q_2^0 \sec \lambda_i \text{ mit } i = 4 - 8 \end{aligned}$$

in pc ausgedrückt.

Die scheinbaren Halbmesser in  $\square'$  werden bezeichnet durch  $\Theta'_i$ . Wenn sie als kreisförmige flache Scheiben angenommen werden, so ist der mittlere scheinbare Radius für die acht Gruppen

$$\Theta'_i = \sqrt{\frac{f'_i}{\pi}}.$$

Der wahre Halbmesser  $\Theta_i$ ,

$$\Theta = \Theta_i = q_i \sec \lambda_i \Theta'_i \sin 1' = q_i \sec \lambda_i \sqrt{\frac{f'_i}{\pi}} \sin 1' = q^0 \sqrt{\frac{f'_i}{\pi}} \sec^2 \lambda_i \sin 1'.$$

Wären die Bedingungen gleicher absoluter Größe für die acht Gruppen der DW erfüllt und sie längs zwei konzentrischen Kreisen um das Zentrum der Milchstraße mit den Abständen  $q_1^0$  und  $q_2^0$  von der Sonne aufgereiht, so müßten die Verhältnisse  $\frac{\Theta}{q_1}$  bzw.  $\frac{\Theta}{q_2}$  (das erste für die Gruppen I, II, III, das zweite für die Gruppen IV, V, VI, VII, VIII) identisch sein. In Fig. V sind die Abstände  $q_1^0$  und  $q_2^0$  gleich groß gezeichnet, was natürlich nicht notwendig ist. Die Dimensionen von  $\Theta$  und  $q$  sind parsec.

Tabelle 16

$$\frac{\Theta}{q^0} = \sqrt{\frac{f'_i}{\pi}} \sec^2 \lambda_i \sin 1' \text{ bei } q_0 = 250 \text{ pc}$$

|      | $\lambda$ | Nördliche Zone | Südliche Zone | Zentrale Zone |
|------|-----------|----------------|---------------|---------------|
| I    | 359°6     | 0.39           | 0.33          | 0.32          |
| II   | 27.8      | 0.30           | 0.38          | 0.42          |
| III  | 59.4      | 0.72           | 1.07          | 1.01          |
| V    | 128.9     |                | 0.70          | 0.57          |
| VI   | 171.9     | 0.36           | 0.34          | 0.28          |
| VII  | 204.6     | 0.37           | 0.35          | 0.33          |
| VIII | 227.8     | 0.77           | 0.75          | 0.77          |

Die Gruppen I, II, VI und VII zeigen eine gute Übereinstimmung untereinander. Die Gleichheit der wahren Halbmesser dieser Gruppen kann so gedeutet werden, daß das Sonnensystem beiderseits von einem Wolkenzuge umhüllt ist, der sich in beiden Richtungen, zum galaktischen Zentrum und zu dessen Gegenpunkte gleich weit erstreckt, und für den die mittlere Größe der Einzelwolken bei 0.4 pc liegt. Die Wolkengruppen III, V und VIII haben entweder größere Dimensionen oder liegen in geringeren Abständen

als der erstgenannte Arm. Der Abstand  $q^{\circ} = 250$  pc ist natürlich willkürlich gewählt und beeinflußt die errechneten wahren Halbmesser entsprechend. Zu beachten ist, daß die Wolken von großen Dimensionen aus dieser Statistik ausgeschlossen sind, in die nur DW, deren Fläche kleiner ist als  $400 \square' = 0.10 \square^{\circ}$  eingehen. Die Anzahl der größeren DW ist aber sehr gering und beträgt im ganzen Katalog nur 20. Sie liegen voraussichtlich in Entfernungen  $< 100$  pc. Zu beachten ist auch noch, daß wir die galaktischen Breiten ( $\delta$ ) unserer acht Gruppen nicht berücksichtigt haben.

Das ganze Band der DW ist, wie unsere Fig. IV zeigt, gegen den galaktischen Äquator um etwa  $2^{\circ}$  südlich verschoben. In unserer Gruppe V gehen überhaupt keine DW in die nördl. Zone ein. Die Absolutwerte der Halbmesser sind bei den Gruppen V und VIII nur wenig abweichend, so daß hier vielleicht ein anderer Arm der DW angedeutet ist.

Die Gruppe IV haben wir aus der Betrachtung ausgeschlossen, weil für sie die Abweichung der DW von der Annahme planparalleler Scheiben sich sehr stark auswirken muß, da die Gesichtslinie bei ihr in der Ebene der größten Ausdehnung liegt.

## XVI. Die Massen und die Dichten der DW

Mit einem Wert für die mittleren Halbmesser der DW kann jetzt auch ihre mittlere Dichte und auch die mittlere Masse abgeleitet werden. Dabei wird, wie üblich, die beobachtete Absorption dem staubförmigen festen Anteil dieser Masse zugeschrieben. Nach Schalén<sup>1</sup> kann dieser Anteil als das Produkt einer von der Wellenlänge unabhängigen Größe  $C$  und der Verfärbungsfunktion  $\psi_{\lambda}(d)$  dargestellt werden

$$\Delta m_{\lambda} = C \psi_{\lambda}(d) \quad (1)$$

$$\text{wo } C = 2.5 \lg e \pi^2 d^3 NH. \quad (2)$$

Hier ist  $N$  die Anzahl der Teilchen pro  $\text{cm}^3$ ,  $H$  die Länge der Strecke innerhalb der DW und  $d$  der Durchmesser der Teilchen.

Die Werte der Funktion  $\psi_{\lambda}(d)$  sind von Schalén für die Metalle Eisen und Nickel und verschiedene Größen der beugenden Partikel ( $d$ ) berechnet worden. Wir entnehmen Schaléns Rechnungen für die photographische Wellenlänge  $\lambda = 0.425 \mu$  und  $d = 80 \mu\mu$  den Wert

$$\psi_{425}(d) = 2.02.$$

Bei den gemachten Voraussetzungen über die Zusammensetzung der DW aus Eisen- und Nickelpartikeln obiger mittlerer Größe kann damit aus (1) die Konstante  $C$  und aus (2) die Anzahl der Teilchen berechnet werden:

$$N = \frac{C}{2.5 \lg e \pi^2 d^3 H}.$$

Bezeichnet noch  $s$  das spezifische Gewicht der Teilchen, so erhält man einen Ausdruck für die mittlere Dichte  $\bar{\rho}$

$$\bar{\rho} = \frac{1}{6} \pi d^3 N s = \frac{C s}{15 \pi \log e H} = \frac{\Delta m s}{\psi_{\lambda}(d) 15 \pi \log e H}. \quad (3)$$

---

<sup>1</sup> C. Schalén, Beiträge zur Theorie der interstellaren Absorption. Uppsala Astron. Observatory Annal. B I, N 2 (1939).

Vergleicht man nun DW verschiedener absoluter Größe ( $\Theta$ ) und findet die Absorption  $\Delta m$  von dieser Größe unabhängig (siehe hierzu die Fig. VI auf S. 28), so kann das Ergebnis

$$\bar{\varrho}H = \text{const.}$$

am einfachsten durch *gleiche Höhen und gleiche Dichten der DW verschiedener Ausdehnung* erklärt werden, d. h. der Zug der DW mit der Form einer durchbrochenen Stratuswolkenschicht unserer Atmosphäre verglichen werden.

Ist aber bei DW verschiedener absoluter Größe die Höhe  $H$  der vom Sehstrahl durchlaufenen Schicht verschieden, so folgt aus konstantem  $\Delta m$  eine zur Höhe umgekehrt proportionale Änderung der Dichte.

Die Massen der DW ergeben sich bei zylindrischer Form zu

$$M = \pi \Theta^2 H \bar{\varrho} = \frac{\Delta ms \Theta^2}{15 \psi(d) \lg e} \quad (\text{C})$$

und bei kugelförmiger Form

$$M = \frac{1}{6} \pi \Theta^3 \bar{\varrho} = \frac{1}{90} \frac{\Theta^3 \Delta ms}{\psi(d) \lg e H}.$$

Da die mittlere die Kugel schneidende Sehne  $H = \frac{2}{3} \Theta$ ,

$$M = \frac{1}{60} \frac{\Theta^2 \Delta ms}{\psi(d) \lg e},$$

d. h. in beiden Fällen proportional zum Quadrate des Halbmessers.

Da wir uns nach den Ergebnissen der früheren Kapitel für die Annahme flacher Scheiben als Form der DW entschlossen haben, berechnen wir nun auch die Masse einer typischen DW unseres Kataloges bei dieser Annahme (C). Wir nehmen für den Abstand  $q_0$ , entsprechend unserer Tabelle einer typischen DW,  $q_0 = 250$  pc. Für die mittlere Absorption setzen wir  $\Delta m = 0.75$ , für das spez. Gewicht  $s = 8$  und als wahre Größe  $\Theta = 0.5$  pc  $= 1.5 \times 10^{18}$  cm.

Dann ergibt sich für die Masse

$$M = 1.0 \times 10^{23} \text{ gm.}$$

Um dieses Ergebnis für die Masse mit demjenigen meiner ersten Arbeit über die Massen von 28 DW der südl. Milchstraße zu vergleichen, tragen wir unsere Zahlen in die logarithmische Gleichung (C)

$$\lg M = \lg \frac{\Delta ms}{15 \psi(d) \lg e} + 2 \lg \Theta$$

ein und erhalten dann

$$\lg M = -0.34 + 2 \lg \Theta.$$

Sie stimmt mit der in jener Arbeit (Seite 38) erhaltenen

$$\log M = 1.90 \log r - 0.34$$

sehr gut überein. Dabei erstrecken sich die Durchmesser der dort vermessenen DW von 0.8 bis 7.6 pc, während die typische DW unseres Kataloges den Halbmesser von 0.5 pc hat. Das Ergebnis: Die quadratische Abhängigkeit der Massen von dem Halbmesser der DW ist damit für ein Gebiet von 0.1 bis 7.6 pc bestätigt.

Die Dichte einer typischen DW unseres Kataloges berechnen wir nach (3) bei denselben Voraussetzungen wie oben zu

$$\bar{\varrho} = 1.1 \times 10^{-24} \text{ g/cm}^3.$$

Wir bringen noch die beiden Diagramme der ersten Arbeit für  $\Delta m_b$  und  $\log M$ , nachdem wir in dieselben als Kreuze den Wert der Masse  $M$  und die mittlere Absorption der typischen DW unseres Kataloges eingetragen haben. Diese Kreuze haben natürlich ein ganz anderes Gewicht als die Einzelwerte der 28 DW, passen aber in den Verlauf der Punkte der ersten Arbeit sehr gut.

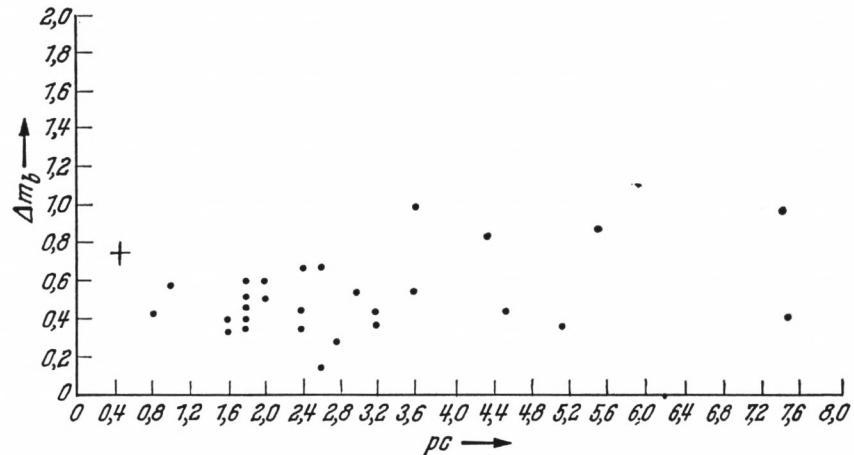

Fig. VI: Die Absorption ( $\Delta m_b$ ) als Funktion des Halbmessers (pc)

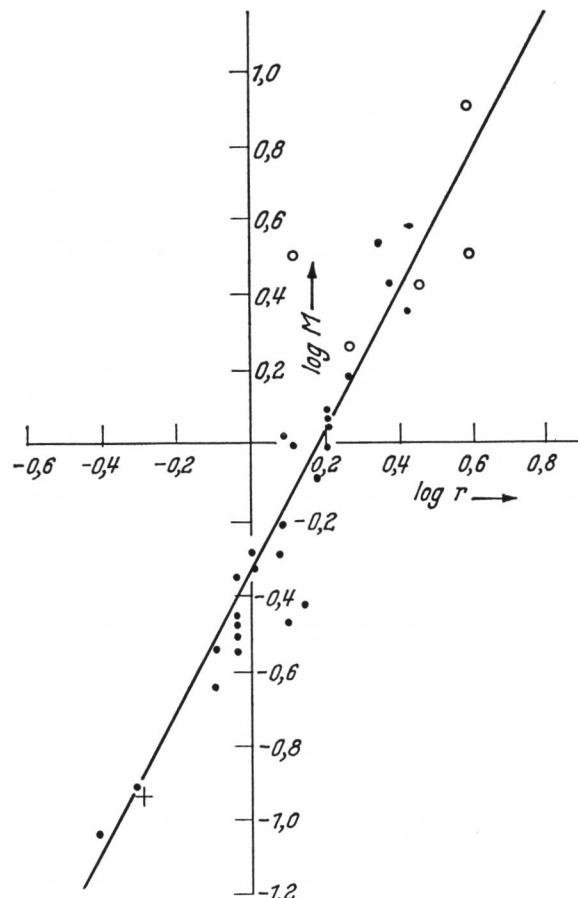

Fig. VII: Die Beziehung zwischen Massen ( $M$ ) und Halbmesser der DW ( $r$ )

## XVII. Die Anzahl der DW als Funktion der scheinbaren Ausdehnung

Die scheinbaren Flächen der DW sind im Katalog in  $\square'$  ausgedrückt. Sie beziehen sich, wie ein Vergleich mit dem Katalog von Barnard und dem Katalog von Chawtasi<sup>2</sup> zeigt, auf den zentralen, dichtesten Teil der DW. Barnard,<sup>1</sup> der die Originalplatten in Durchsicht benutzte, hat auch die äußereren, schwächeren Teile der DW erfaßt. Leider gibt es nur wenige DW, die unseren Katalogen gemeinsam sind. Das liegt zum Teil daran, daß bei meinen Messungen die sehr stark anwachsende Zahl der kleinsten DW bis zu Flächen von  $0.01 \square'$  mit vermessen sind, wenn sie in den Atlanten von Roß und Lick in derselben Form feststellbar waren. Das entsprach einem linearen Durchmesser in beiden Atlanten von 1 mm und war bei fünffacher Vergrößerung gut von Sternlücken zu unterscheiden. Die beiden genannten Kataloge beziehen sich auf größere DW, derjenige von Chawtasi sogar nur auf DW, die  $> 0.1 \square'$ . Dadurch ist die Zahl der identischen DW bei Barnard und mir nur 26, für die das Verhältnis der Flächen sich zu

$$B : S = 1.98 \text{ in linearem Maße zu 1.4}$$

ergab. Wegen der größeren Zuverlässigkeit der Durchmessermessungen von Barnard habe ich durch den Faktor 2 meine Flächenmessungen auf diejenigen von Barnard reduziert. Die Auszählung der Anzahl der DW verschiedenen Flächeninhalts meines Kataloges ergab folgende Zahlen.

Tabelle 17

Mittelwerte für die Anzahl der DW verschiedenen Flächeninhalts

| Grenzen der Fläche in $\square'$ | Mittl. Fläche                   | Anzahl $N$ |
|----------------------------------|---------------------------------|------------|
| 0–40                             | $20 \square' = 0.0055 \square'$ | 469        |
| 40–80                            | $60 = 0.0167$                   | 452        |
| 80–120                           | $70 = 0.0278$                   | 208        |
| 120–160                          | $140 = 0.0398$                  | 104        |
| 160–200                          | $180 = 0.0500$                  | 86         |
| 200–240                          | $200 = 0.0555$                  | 41         |
| 240–280                          | $260 = 0.0722$                  | 38         |
| 280–320                          | $300 = 0.0833$                  | 20         |
| 320–360                          | $340 = 0.0944$                  | 12         |
| 360–400                          | $380 = 0.1056$                  | 11         |
| 400–500                          | $450 = 0.1250$                  | 17         |
| 500–600                          | $546 = 0.1516$                  | 13         |
| 600–700                          | $668 = 0.1856$                  | 1          |
| 700–800                          | $760 = 0.2111$                  | 5          |
| 800–1000                         | $858 = 0.2383$                  | 5          |
| 1000–1200                        | $1040 = 0.2889$                 | 4          |
| 1200–1400                        | $1308 = 0.3634$                 | 3          |
| 1400–1600                        | $1436 = 0.3989$                 | 1          |
| 1600–1800                        | $1676 = 0.4656$                 | 3          |
| 2000–3000                        | $2500 = 0.6945$                 | 2          |
| 3000–4000                        | $3146 = 0.8740$                 | 3          |
| 4000–6000                        | $5212 = 1.4478$                 | 1          |

<sup>1</sup> A Photographie Atlas of selected regions of the Milky Way. Public. Carnegie Institution Nr. 207 (1927).

Der plötzliche Sprung der Anzahl  $N$  bei den kleinsten DW ist nicht reell. Bei den kleinsten war es sehr schwer, dieselben von den Lücken des Sterngrundes zu unterscheiden. Daher ist die Anzahl derselben wesentlich zu klein gezählt. Unter Weglassung der ersten Zahl zeigt das graphische Bild eine glatt verlaufende Kurve, die man sehr genau durch eine Hyperbel von der Form

$$\frac{K}{\sigma - \sigma_0} = \frac{K}{s} = N(s) \quad (\text{A})$$

bei  $K = 1.404$ ,  $\sigma_0 = 0.023$ , wo  $\sigma - \sigma_0 = s$  gesetzt ist, darstellen kann. Letztere ist in Fig. VIII durch Punkte, die beobachteten Anzahlen durch Kreuze bezeichnet. Der Punkt der größten Krümmung der Hyperbel ist stark von dem Vergrößerungsfaktor der gemeinsamen Flächen der DW abhängig, für den wir 2.0 aus dem Vergleich mit dem Barnard-Katalog angenommen haben. Chawtasi, der nur DW, die  $> 0.10 \square^{\circ}$  sind, gemessen hat, findet als Frequenzkurve ebenfalls eine Hyperbel von wesentlich flacherer Form.

## XVIII. Die Frequenzkurve der wahren Flächen der DW

Man kann die Frequenzkurve der wahren Flächen

$$\varphi(r^2 s)$$

aus der Frequenzkurve der scheinbaren  $N(s)$  mit Hilfe der Integralgleichung der Stellarstatistik ableiten. Die Dichte in der Raumeinheit  $\omega$  sei durch  $D(r)$  bezeichnet. Dann ist die Gleichung der Stellarstatistik

$$N(s) = \omega \int_0^\infty r^4 D(r) \varphi(r^2 s) dr = \frac{K}{s}. \quad (\text{B})$$

Als obere Grenze des Integrals setzen wir  $R = 700$  pc und führen die neue Variable

$$\begin{aligned} r^2 s &= x \text{ ein, wobei dann die obere Grenze} \\ R^2 s &= X \text{ wird.} \end{aligned}$$

Die Dichte auf der kleinen Strecke  $R$  soll als konstant betrachtet werden  $D_0$ . Dann ist

$$r^4 dr = \frac{x^{3/2} dx}{2 s^{3/2}} \text{ und}$$

$$\frac{K}{s} = \omega D_0 \int_0^X \frac{x^{3/2}}{2 s^{3/2}} \varphi(x) dx$$

$$s^{3/2} = \frac{\omega D_0}{2 K} \int_0^X x^{3/2} \varphi(x) dx = \frac{X^{3/2}}{R^3}.$$

Differenziert man beide Seiten dieser Gleichung nach  $X$

$$\frac{3}{2} X^{\frac{1}{2}} = \frac{\omega D_0 R^3}{2 K} X^{\frac{3}{2}} \varphi(X) \text{ und löst man nach } \varphi(X)$$

auf

$$\varphi(X) = \frac{1}{X} \cdot \frac{3K}{\omega D_0 R^3};$$

$$\varphi(r^2 s) = \frac{3K}{\omega D_0 R^3} \cdot \frac{1}{r^2 s}. \quad (\text{C})$$

Die Gleichung zeigt, daß auch die Frequenzkurve der absoluten Größen der DW hyperbolische Form hat.

Für eine numerische Auswertung der Formel (B) und (C) brauchen wir einen Wert für die Raumdichte  $D_0$ . Wir approximieren den Milchstraßengürtel durch ein Band, das sich über die galaktischen Längen von  $225^\circ$  erstreckt und eine Breite von  $12^\circ$  besitzt. Diese Zahlen entsprechen im Durchschnitt den galaktischen Längen und Breiten des Gebietes, in dem die DW des Kataloges liegen. Der Radius dieser Zone wird zu  $R = 700 \text{ pc}$  angenommen und die Anzahl der in diese Statistik aufgenommenen DW zu  $N = 1000$ . Dann ergibt sich

$$D_0 = \frac{N}{0.625 \pi R^2 2 R \operatorname{tg} 6^\circ} = 7.1 \times 10^{-6} \quad (\text{C})$$

$$D_0 \omega R^3 = 7.1 \times 10^{-6} \times 3.045 \times 10^{-4} \times 343 \times 10^6 = 0.74 \quad (\text{D})$$

$$\varphi(sr^2) = \frac{4.2}{D_0 \omega R^3} \cdot \frac{1}{sr^2} = \frac{5.68}{sr^2}. \quad (\text{E})$$

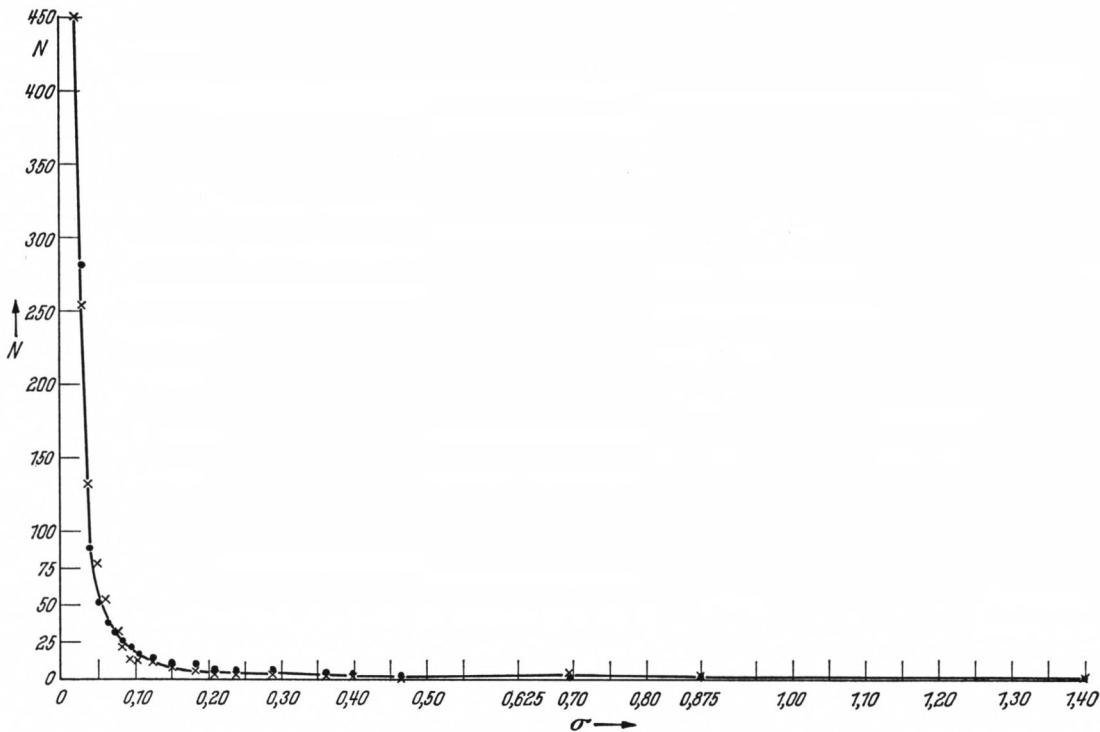

Fig. VIII: Anzahl der DW  $N$  als Funktion der Flächen  $\sigma$

Wir berechnen die Anzahl der DW auf  $1 \square^\circ$  des Milchstraßengürtels, der  $2700 \square^\circ$  enthält, aus (A) zu

$$N(s) = \frac{1.4}{2700 s} = \frac{5.2 \cdot 10^{-4}}{s}$$

durch Integration über die Flächen  $s$  von  $0^{\circ}.001$  bis  $1.0 \square^\circ$

$$N(1 \square^\circ) = \int_{0.001}^{1.0} N(s) ds = 1.56 \times 10^{-3}. \quad (\text{F})$$

Die folgenden zwei Tabellen veranschaulichen den Verlauf der Funktionen  $sr^2$  für die wahren Flächen in  $(\text{pc})^2$  und für die Frequenz der wahren Flächen  $\varphi(sr)^2$  in verschiedenen Abständen von der Sonne in der ganzen beobachteten Zone.

| $r$    | $sr^2$                |               |        |        |         |        |         |        |         |  |

## Die Konstanten der Roß- und Lickblätter, die für die Ortsbestimmung der DW benutzt wurden

Die Konstanten  $a, b, c, d, e, f$  in der Turnerschen Formel

$$X = ax + by + cz,$$

$$Y = dx + ey + fz,$$

wo  $x$  und  $y$  die gemessenen linearen Koordinaten der DW sind, mit deren Hilfe die sphärischen Koordinaten  $\alpha_{1950}, \delta_{1950}$  abgeleitet wurden. Die Koordinaten des Zentralpunktes jedes Blattes  $A$  und  $P$  (Rektaszension und Poldistanz), sowie die 6 Konstanten  $a, b, c, d, e, f$ , werden hier für jedes vermessene Blatt angeführt. Es stehen immer die Konstanten derjenigen Blätter beider Atlanten untereinander, die für die Ortsbestimmung derselben DW benutzt wurden.

Unter den Konstanten und den Koordinaten der Plattenzentren  $A$  und  $P$  sind noch die systematischen Korrekturen der sphärischen Koordinaten  $\Delta R_\alpha, \Delta R_\delta, \Delta L_\alpha, \Delta L_\delta$  angeführt (R und L bezeichnen Roß- und Lickblätter), die sich aus der Reduktion der unabhängig gefundenen Werte von  $\alpha$  und  $\delta$  auf einen Mittelwert ergaben. Diese systematischen Korrekturen sind in den Katalogörtern schon angebracht. Zusammengestellt sind die Konstanten derjenigen Roß- und Lick-Blätter, die gemeinsame DW enthalten, deren Örter im Katalog neben ihrem Mittelwert angeführt sind.

Da die Roß- und Lick-Blätter bis zu  $40^\circ$  in  $\delta$  umfassen, ist bei hohen  $> 50^\circ$  Deklinationen das Turnersche Verfahren für randnahe DW bei der erstrebten Genauigkeit von  $\pm 1'$  ungenügend. Das ist bei den Gruppen I, II, III, IV, XVII und XVIII der Fall. Hier wurde ein graphisches Verfahren für die Korrektion der nach den obigen Formeln abgeleiteten Örter angewandt.

Die systematischen Korrekturen  $\Delta R$  und  $\Delta L$  sind Reduktionen der einzelnen Blätter auf den Mittelwert aus allen, auf denen die DW vermessen waren. In Fällen, wo nur 2 Örter vorlagen, wie bei den Gruppen II, III und IV, ist einfach der Mittelwert aus dem Roß- und dem Lick-Ort gebildet, weshalb keine systematischen Korrekturen möglich waren.
