Key words: Vinca sardoa, laticifers, alkaloid location.

Summary

SACCHETTI G., BALLERO M., SERAFINI M., ROMAGNOLI C., BRUNI A. & POLI F. 1999. Laticifer tissue distribution and alkaloid location in *Vinca sardoa* (STEARN) PIGN. (*Apocynaceae*), an endemic plant of Sardinia (Italy). – Phyton (Horn, Austria) 39 (2): 265–275, with 17 figures. – English with German summary.

Vinca sardoa (*Apocynaceae*) is an endemic plant of Sardinia (Italy) used in local folk medicine. Yet it has never been described in detail, particularly in regard to its secretory structures. The present research uses optical and electron microscopy to detect the laticifer cells in all plant organs, including the roots, where such cells had never previously been reported. Moreover, as opposed to what has been described in similar studies, these laticifer cells are articulated. In addition, histochemical tests

were performed to detect the alkaloids in the latex and to quickly identify the same laticifer tissues in fresh samples. These tests always proved positive, indicating a close relationship between laticifer cells and the presence of alkaloids in the plant. TEM also showed that the laticifer cells have well-preserved cytoplasm and organelles which lead one to conclude that metabolic activity is still intact.

Zusammenfassung

SACCHETTI G., BALLERO M., SERAFINI M., ROMAGNOLI C., BRUNI A. & POLI F. 1999. Die Verteilung von Geweben mit Milchröhren und die Lokalisation von Alkaloiden in *Vinca sardoa* (STEARN) PIGN. (*Apocynaceae*), einer endemischen Pflanze Sardiniens (Italien). – Phyton (Horn, Austria) 39 (2): 265–275, 17 Abbildungen. – Englisch mit deutscher Zusammenfassung.

Vinca sardoa (Apocynaceae) ist eine endemische Pflanze Sardiniens (Italien) und wird in der örtlichen Volksmedizin verwendet. Bisher wurde sie noch nie genau, insbesondere im Hinblick auf ihre sekretorischen Strukturen, beschrieben. Diese hier vorliegende Untersuchung setzt Licht- und Elektronenmikroskopie ein, um die Milchsaftzellen in allen Pflanzenorganen, einschließlich Wurzeln zu ermitteln; daß solche Zellen auch in Wurzeln vorkommen, wurde bisher noch nicht berichtet. Darüberhinaus, im Gegensatz zu dem was in ähnlichen Studien früher beschrieben wurde, sind diese Milchröhren gegliedert. Zusätzlich wurden histochemische Tests durchgeführt, um die Alkaloide im Milchsaft zu erkennen und um schnell die Milchröhren in frischen Proben nachzuweisen. Diese Tests fielen immer positiv aus und belegen damit den engen Zusammenhang von Milchröhren und dem Vorliegen von Alkaloiden in der Pflanze. TEM zeigte ebenfalls, daß die Milchsaftzellen ein gut erhaltenes Cytoplasma besitzen und Organellen, von denen man schließen kann, daß die Stoffwechselaktivität noch aufrecht ist.

Introduction

Vinca sardoa (Stearn) Pign. (Apocynaceae) is a species native to Sardinia which has never been subject to in depth study. In Sardinian folk medicine this plant is known for its hypotensive, astringent, hemostatic and depurative properties (ATZEI & PICCI 1975). The purpose of the present work has been to determine the distribution and location of laticifer vessels in the plant and histochemically detect the alkaloids present in the latex. Preliminary phytochemical studies had previously shown that various alkaloids were present in the above-ground portion of the plant (NICOLETTI & al. 1998). TEM was then used to characterize the ultrastructural features of the cells secreting and storing the latex.

Materials and Methods

Plant material

Vinca sardoa (Stearn) Pign. (Apocynaceae) plants were collected in Sardinia on the Marganai-Linas massif (Cagliari, Italy) at full flowering (March-May). The plants were identified following the keys reported in "Flora d'Italia" (PIGNATTI 1982) by M. BALLERO and a representative specimen of the species was deposited in the *Herbarium* of the Institute of Botany and Botanical Garden, University of Cagliari (CAG. no. 1301).

The number of plants examined and processed for conventional and electron microscopy was 50.

Conventional microscopy

Fresh cross and longitudinal sections of each plant organ were cut by hand using razor blades. These sections were stained for the identification of the laticifers alkaloid content and then examined under bright field. The following staining solutions were employed: Ellram reagent (FURR & MAHLBERG 1981), chloroauric acid (HAuCl₄), iodine-potassium iodide (IKI) (JOHANSSEN 1940), phosphotungstic acid (MORELLI 1981). All sections were stained for 24 h before observation. Negative controls were prepared by setting sections of each plant organ in a tartaric acid 10 % alcoholic solution for 24 h and then treating them with alkaloid indicators, following the suggestions given by the respective authors.

Samples of roots, stems, petioles, leaves and flowers were then fixed, embedded and sectioned following the procedures reported in POLI & al. 1995. Toluidine blue O (FEDER & O'BRIEN 1968) was used as general stain and Ninhydrin-Shiff's reaction (BRUNI & al. 1982) was used to detect cytoplasmic proteins. After staining, the sections were studied by a Zeiss Axiophot photomicroscope.

Transmission Electron Microscopy (TEM)

The same kinds of samples were fixed and processed for TEM following the standard procedures reported in Poll & al. 1989. A Zeiss electron microscope EM 109 N was used for observations.

Results

Histochemical and histological data

Conventional optical microscopy was used to observe sections of roots, stems, petioles, leaves and flowers of *Vinca sardoa*. This study revealed laticifer cells throughout the entire plant. The histochemical reactions indicated that alkaloids are stored in the laticifers of all the plant organs (Table 1).

+ weak reaction; ++ moderate reaction; +++ intense reaction.

There were numerous laticifer cells which appeared dark and weré distributed throughout the cortical region of the roots (Figs. 1–2). Histochemical reaction with chloroauric acid solution (HAuCl₄) on longitudinal sections stained the latex a deep purple-red revealing numerous unbranched, articulated laticifers distributed throughout the entire cortical region (Fig. 2). The iodine-potassium iodide solution (IKI) stained the latex a deep brown-red evidencing the laticifers in the cortical area (Fig. 2a).

In the stem the laticifers were located in the cortical region, both close to the vascular bundles and below the epidermis. In the cross-sections, a comparison of the laticifer cells with the surrounding cells showed that the former were round and generally larger (Fig. 3). Alkaloid-specific reactions indicated that alkaloids were indeed present in the latex compounds (Fig. 4), while the same histochemical tests gave negative results on sections pretreated with tartaric acid (controls) (Fig. 5). The longitudinal stem sections showed unbranched and articulated laticifers with different alkaloid reactivity in the laticifer cells below the epidermis and close to the

270

vascular bundles (Figs. 6, 7). In this part of the plant, the Ninhydrin-Schiff's protein reaction indicated a greater accumulation of proteins in the laticifer cell cytoplasm than in the surrounding cells (Fig. 8).

Cross-sections of resin-embedded petiole specimens showed numerous laticifer cells both below the epidermis and in the phloem parenchyma (Fig. 9). In fresh samples, the histochemical reactions clearly detected the presence of alkaloids in laticifer cells (Fig. 10). HAuCl₄ produced a particularly intense stain of the laticifers below the epidermis (Fig. 10a).

Cross-sections of fresh and resin-embedded leaf specimens revealed laticifer cells, particularly close to the abaxial surface just below the epidermis (Fig. 11). No particular interaction between laticifer vessels and vascular bundles were found here. In the fresh sections the alkaloid indicators reacted with the latex producing an intense stain (Fig. 11a).

In the flower, the laticifer vessels were present in the corolla while they were absent in both the androecium and the gynoecium. Crosssections of resin-embedded samples revealed laticifer cells below the epidermis and in the parenchyma between the vascular bundles (Figs. 12, 13). Fresh longitudinal sections, treated with chloroauric acid solution, showed a strongly purple-red stain (Fig. 14).

Ultrastructural data

The ultrastructural characteristics of the mature laticifer cells were similar in all plant organs. The present data refer to the mature laticifer cells in the stem as these were best preserved by the fixing and embedding

intensely stained the laticifer latex below the epidermis (e). Scale bar = 50 μ m. Fig. 11. Laticifers in the leaves of *V. sardoa*. Resin-embedded cross-section of the leaf stained with TBO. The arrow indicates a laticifer cell (a: abaxial surface). Scale bar = 100 μ m. Fig. 11a. Hand-cut cross-section of the leaf stained with IKI solution. The latex in the laticifers is strongly stained a brown-red (a: abaxial surface). Scale bar = 50 μ m.

method. The mature laticifer cell has a large central vacuole full of latex accumulated in a large osmiophilic droplet. Part of the latex, in the form of smaller droplets, also adhered to the tonoplast (Fig. 15). The vacuole was surrounded by a thin layer of well-preserved parietal cytoplasm. Plastids, mitochondria and RER profiles appeared well-structured and showed no signs of degradation (Fig. 16). In particular, the laticifer cell plastids held numerous osmiophilic droplets, while the plastids in the surrounding parenchymal cells contained only starch (Fig. 17).

Discussion

All the organs in Vinca sardoa presented unbranched, articulated laticifer tissues while unbranched, non articulated laticifer tissues have been reported for the genus Vinca, as for all Apocynaceae (METCALFE 1967, FAHN 1979). In particular, FAHN 1979 asserts that laticifer cells are not present in the roots of plants belonging to the genus Vinca. The present results, however, show numerous laticifer cells throughout the entire cortical parenchyma in the roots of V. sardoa. In the stem and leaves, on the other hand, these secretory structures showed the same distribution pattern as reported for other Vinca species, i.e. mainly located in the cortical portion, between the epidermis and close to the vascular bundles (METCALFE 1967). Indeed, in our opinion, the distinctive structure and distribution of laticifer cells emphasizes the particularity of this species as it differs V. minor and the genus as a whole in the laticifer system distribution and structure. This unique data can be further added to the morphological-systemic features which have led taxonomists to suggest a new species (PIGNATTI 1982). In fact, V. sardoa was, until recently, considered a variety in the species V. difformis (ATZEI & PICCI 1975).

The histochemical reactions for alkaloids proved positive in all plant organs although to different extents. This indicates an evident correlation between the laticifer structures and the presence of alkaloid compounds. On the other hand, the difference in alkaloid reactivity found in the stem laticifer cells below the epidermis and close to the vascular bundles can, most likely, be explained by the different degree of alkaloid accumulation

Figs. 15–17. TEM micrographs of mature laticifers in the stem of *V. sardoa*. Fig. 15. The mature laticifer cell presents a large vacuole filled with latex gathered in a large osmiophilic droplet (od). The arrows indicate the latex adherent to the tonoplast. Scale bar = 1 μ m. Fig. 16. The vacuole (v) appears surrounded by a thin layer of well-preserved parietal cytoplasm containing RER (rer), plastids (p) and mitochondria (m). The arrowheads indicate trace of osmiophilic droplets in the plastid lost during TEM procedures. Scale bar = 1 μ m. Fig. 17. The parenchymal cell adjacent to the laticifer (above) reveals well-structured plastids containing droplets of starch (s). The plastid in the young laticifer cell (below) contains osmiophilic droplets (arrow-

heads). Scale bar = $1 \mu m$.

in the latex. Our data, together with those of similar research (CORSI & BIASCI 1998), support preliminary phytochemical findings regarding the isolation and identification of alkaloids in plants. The findings derived from optical, and above all, transmission electron microscopy performed on all plant laticifers has not, however, shown any significant structural differences between the laticifer cells in the various organs. TEM findings revealed cells with well-preserved, normally structured organelles. This type of ultrastructural organization appears to indicate elevated protein synthesis, as optical microscopy had revealed in the histochemical cytoplasmic protein reaction. Similar findings regarding protein synthesis in laticifer tissues at a particular stage of differentiation have been observed in Euphorbia marginata (BRUNI & al. 1982). As regards the presence of osmiophilic granules in laticifer cell plastids, in light of the above findings, it is not possible to determine whether these are latex precursors or simply the plastoglobuli located in many plant species (BACKHAUS & WALSH 1983). On the other hand, the possibility that plastids play a role in the synthesis of lipophilic substances (FAHN 1979) and in the biosynthesis of terpenes in general, has already been demonstrated (GRUMBACH & FORN 1980).

This kind of work about histochemical localization of alkaloids will help to correlate the phytochemical information (NICOLETTI & al. 1998) with the site and structure where these metabolites are produced and/or stored.
