**A new cryptic treefrog species
of the *Boophis luteus* group from Madagascar:
bioacoustic and genetic evidence**

(Amphibia, Anura, Mantellidae)

Frank Glaw & Miguel Vences

Glaw, F. & M. Vences (2002): A new cryptic treefrog species of the *Boophis luteus* group from Madagascar: Bioacoustic and genetic evidence (Amphibia, Anura, Mantellidae). – Spixiana 25/2: 173–181

We describe a new sibling species of *Boophis ankaratra* from Madagascar: *Boophis schuboeae*, spec. nov. from the Ranomafana National Park in south-eastern Madagascar. The new species belongs to the *Boophis luteus* group, which is composed of green treefrogs of low morphological differentiation. Analyses of advertisement calls and of partial sequences of the mitochondrial 16S rRNA gene evidenced a high bioacoustic and genetic uniformity throughout the range of *B. ankaratra*, while *B. schuboeae* was genetically divergent (2.4–2.8 % pairwise difference) and had distinct temporal and spectral call differences. The colour patterns of *B. schuboeae* are similar to those of *B. andohahela* from far south-eastern Madagascar. Re-analyses of advertisement calls, however, indicate that this species is bioacoustically highly different and close to *B. jaegeri* from the north-west, confirming that external morphology in the *B. luteus* group is not reliable to assess relationships.

Introduction

Among the anurans of Madagascar, the green-coloured species of the treefrog genus *Boophis* belong to the taxonomically most complicated groups. The reasons lie in the large number of morphologically similar cryptic species, and in the fact that the often species-specific life coloration fades quickly in preservative to a largely uniform pale yellow colour. This applies to two of the seven phenetic species groups (Blommers-Schlösser & Blanc 1991, Glaw & Vences

1994): the *Boophis rappiodes* group and the *B. luteus* group. The *B. luteus* group has experienced a dramatic increase in recognized species diversity during the last decade. While only a single species, *B. luteus*, was recognized by Blommers-Schlösser & Blanc (1991), ten new species have been described since the application of bioacoustic methods (Andreone 1993, 1996, Andreone et al. 1995, Glaw & Thiesmeier 1993, Glaw & Vences 1992, 1994). Recent molecular work (Vences et al. in press) has demonstrated a rather high genetic differentiation for

a subsample of these taxa, confirming their specific validity.

One of the new species in the *Boophis luteus* group, *B. ankaratra*, was described by Andreone (1993) from Manjakatampo in the Ankaratra massif in central Madagascar. It was later recorded from the Andringitra massif about 320 km south of the type locality (Glaw & Vences 1994). Recent fieldwork has yielded records of several additional localities of this species at sites above 1000 m elevation in central eastern Madagascar, and led to the discovery of a bioacoustically divergent population from a mid-altitude site in the Ranomafana National Park. We herein provide bioacoustic and genetic evidence for the status of this population as separate species, thereby adding relevant perspective to the discussion of elevational endemism in Malagasy frogs. Considering the similarity in colour pattern of the new species to *Boophis andohahela*, we additionally provide a re-description of the divergent calls of that species and its bioacoustic sibling *B. jaegeri*.

Materials and methods

Frogs were collected during the night, by means of electric torches, mainly by localizing calling males. They were sacrificed using chlorobutanol, fixed in 5 % formalin or 90 % ethanol, and preserved in 70 % ethanol. Specimens studied in this paper are deposited in the collections of the Université d'Antananarivo, Département de Biologie Animale (UADBA), Zoologisches Forschungsinstitut und Museum A. Koenig, Bonn (ZFMK), and Zoologische Staatssammlung München (ZSM).

Morphological measurements were taken by M. V. using a caliper to the nearest 0.1 mm: SVL (snout-vent length), HW (head width), HL (head length), ED (horizontal eye diameter), END (eye-nostril distance), NSD (nostril-snout tip distance), NND (nostril-nostril distance), TD (horizontal tympanum diameter), HAL (hand length), FORL (forelimb length), HIL (hindlimb length), FOL (foot length), FOTL (foot length including tarsus).

Advertisement calls were recorded with different tape recorders using external microphones. They were analyzed either with a ME-DAV sound analyzing system with the software Spekro 3.2, or on a PC, using the software

Cooledit (Syntrillium Corp.). Temporal and metric measurements are given as range, with mean \pm standard deviation and number of measured units in parentheses.

A fragment of the mitochondrial 16S rRNA gene (up to 559 nucleotides) was amplified and sequenced using primers and protocols of Vences et al. (2000). Sequences were analyzed using PAUP*, version 4b8 (Swofford 2001). They were deposited in public databases; EMBL/Genbank accession numbers are: *Boophis schuboeae* (ZFMK 62907; AJ315912); *Boophis ankaratra*: Andringitra (tadpole, not preserved; AF411611), Col des Tapias (ZSM 399/2000, AJ315910), Itremo (ZSM 735/2001; AF411612), Manjakatampo (ZSM 367/2000, AJ315911), Mandraka (ZSM 400/2000, AJ315909). *Boophis cf. sibilans* (ZSM 327/2000, AJ315913) was used as the outgroup.

Boophis schuboeae, spec. nov.

Figs 1, 2

Types. Holotype: ZFMK 62299, adult male, collected by F. Glaw, D. Rakotomalala and F. Ranaivojaona on 2 March 1996 at Ranomafana National Park (ca. 21°14'S, 47°26'E), close to Ambatolahy, south-eastern Madagascar. – Paratypes: ZFMK 62906-62907, two adult males with same collecting data as holotype; ZSM 1086/2001 (originally ZFMK 62285), adult male, collected by F. Glaw, D. Rakotomalala and F. Ranaivojaona on 28 February 1996 at Vohiparara (Ranomafana National Park, at ca. 1000 m above sea level), south-eastern Madagascar.

Diagnosis. A member of the *Boophis luteus* group as recognizable by the green dorsal coloration with translucent shade in life (shared with the *B. rappiodes* group; opaque green in the *B. albilabris* group and in *B. microtympanum*, not green in other *Boophis* species groups), pigmented ventral side (inner organs not visible in life through a transparent skin as in species of the *B. rappiodes* group) and lateral fringes along lower arm and tarsus (absent in the *B. rappiodes* group). Within the *B. luteus* group, *B. schuboeae* is distinguished by its rather small body size (male SVL <30 mm vs. >34 mm in *B. luteus*, *B. septentrionalis*, *B. elenae*, *B. anjanaharibeensis*, *B. englaenderi*) and presence of light dorsolateral lines (known to occur only in three other species: *B. septentrionalis*, *B. andohahela*, and *B. ankaratra*). General advertisement call structure (regular series of up to 55 unharmonious

Fig. 1. *Boophis schuboeae*, spec. nov. in life.

Fig. 2. *Boophis schuboeae*, spec. nov. in life, ventral view.

notes) is fundamentally different from all species of the *B. luteus* group except for *B. ankaratra*. Differs from *B. ankaratra* by temporal and spectral call parameters (see below and Table 2), and by molecular characters.

Description of the holotype

SVL 26.0 mm. For measurements, see Tab. 1. Body slender; head as long as wide, much wider than body; snout rounded in dorsal and lateral views, nostrils directed dorsolaterally, slightly nearer to eye than to tip of snout; canthus rostralis indistinct; loreal region slightly concave; tympanum distinct, rounded, 47 % of eye diameter; supratympanic fold not recognizable; tongue ovoid, distinctly bifid posteriorly; vomerine teeth present, in two small rounded aggregations, positioned posterolateral to choanae; choanae rounded. Arms slender, subarticular tubercles single; metacarpal tubercles not recognizable; fingers webbed; webbing formula 1 (–), 2i (–), 2e (–), 3i (–), 3e (1.75), 4 (1); relative length of fingers 1<2<4<3, finger 2 distinctly shorter than finger 4; finger disks enlarged; small unpigmented nuptial pads faint-

ly recognizable on inner side of first finger. Hindlimbs slender; tibiotarsal articulation reaches nostril when hindlimb is adpressed along body; lateral metatarsalia separated by webbing; inner metatarsal tubercle recognizable, no outer metatarsal tubercle; webbing formula between toes 1 (0.5), 2i (1), 2e (0), 3i (1.25), 3e (0.5), 4i (1.5), 4e (1.5), 5 (1); relative length of toes 1>2>3>5>4. Skin on the upper surface smooth; ventral skin smooth on throat, very slightly granular on belly; no distinct enlarged tubercles in the cloacal region.

After five years in preservative, uniformly yellowish-white dorsally and ventrally. Two dorsolateral rows of three dark spots each are present on the central dorsum.

Colour in life (based on slides of three males). Upper surface of head, back and flanks green. Small white or yellowish dots can be present on parts of the dorsal surface, and are most distinct on the hindlegs where they can form interrupted crossbands. The dots tend to be more yellowish above the upper lip. A yellow, sometimes incomplete or interrupted line runs from the eye to the nostril and a dorsolateral line of the same colour runs from the posterior eye corner several millimetres posteriorly (virtually absent in one specimen). The iris is golden or yellow with a reddish brown or silvery inner ring. The iris periphery is blue. An indistinct whitish line is present laterally on lower arm und tarsus. Venter white, throat pale greenish-grey to bluish-green, ventral surfaces of arms and legs bluish-green.

Variation. The morphology of the paratypes is very similar to the holotype (see Table 1). Due to tissue sampling for genetic analyses, the left forelimb is lacking in ZFMK 62906 and the right hindlimb is lacking in ZFMK 62907.

Etymology. *Boophis schuboeae* is dedicated to Dr. Anna Schubö, Munich.

Natural history. Calling males were observed at night about 2 m high in the vegetation along brooks in primary forest.

Bioacoustic comparison of *B. schuboeae* (Fig. 3) and *B. ankaratra* (Fig. 4). Call recordings were available of *B. schuboeae* from Ranomafana and Vohiparara, as well as of *B. ankaratra* from all six known localities (see Fig. 5). All these calls consisted of series of regularly repeated notes (but at Mandraka and the Col des Tapias we

Tab. 1. Morphometric measurements (all in mm) of holotype and paratypes of *Boophis schuboeae*. For abbreviations of measured variables, see Materials and methods; RHL (relative hindlimb length) gives the point reached by tibiotarsal articulation when the hindlimb is adpressed along the body.

additionally heard rapid series of 2-3 notes, possibly of territorial function, interspersed between the regular calls). Calls of *B. ankaratra* consisted of 50-105 notes, those of *B. schuboeae* of at least up to 55 notes. Notes were distinctly pulsed and unharmonious to the human ear in *B. ankaratra*, but more melodious and less distinctly pulsed on the oscillogram in *B. schuboeae*. Important differences were furthermore noted in the note repetition rate (Table 2) which was faster (3.3-3.6 notes per second) in *B. schuboeae* than in *B. ankaratra* (2.2-2.8 notes per second; 1.3 in the particularly low motivated Itremo specimens). This difference was caused by a lower duration of intervals between notes in *B. schuboeae* (mean interval duration 127-158 ms vs. 234-671 ms; Table 2). In those notes of *B. schuboeae* in which pulses were recognizable on the oscillograms, pulse number was much higher than in *B. ankaratra* (ca. 50-60 vs. 16-35). No consistent differences in note duration were

noted between both species (Table 2), despite the lower temperature at which most *B. ankaratra* recordings were made. This indicates that the differences observed between both species were not caused by influences of temperature.

Molecular phylogeny and differentiation. The obtained sequences presented no indels and their alignment was therefore possible without inclusion of gaps. 23 nucleotides (nt) in the first and last sections could not be read in one or more sequences and were therefore excluded from the analysis. Of 536 included characters, 479 were constant, 49 were variable but parsimony-uninformative, and eight were variable and parsimony-informative. A Maximum Parsimony analysis (exhaustive search) yielded five equally most parsimonious trees; a strict consensus of those is shown in Fig. 6. The included sequences of *Boophis ankaratra* were grouped as monophylum, strongly supported by bootstrap

Tab. 2. Temporal and spectral characteristics of available calls of *Boophis ankaratra* and *B. schuboeae*. The divergent calls of the Itremo population of *B. ankaratra* were recorded from lowly motivated males late at night when calling activity had almost stopped. Calls heard (but not recorded) earlier the same night had clearly a faster repetition rate by subjective impression.

Species	Locality	Recording date	Recording temperature	Note duration [ms]

analysis (98 %), but relationships between them were not resolved. Total pairwise divergence between *B. ankaratra* sequences was 1-3 nt (0.2-0.6 %), while it was 13-15 nt (2.4-2.8 %) between *B. schuboeae* and *B. ankaratra*.

Advertisement call of *Boophis andohahela* (Fig. 7) and *B. jaegeri* (Fig. 8). Andreone et al. (1995) described the new species *Boophis andohahela* from the rainforests of the Andohahela reserve in far south-eastern Madagascar. This species is characterized by yellowish dorsolateral stripes, and an iris coloration similar to *B. schuboeae*. However, the advertisement calls

of *B. andohahela* as described by Andreone et al. (1995) were similar to those of *B. jaegeri* (Glaw & Vences 1992) whereas Andreone & Randriamahazo (1997) provided partly different call data for *B. andohahela*. To exclude conspecificity of *B. andohahela* and *B. schuboeae*, we re-analyzed the advertisement calls of *B. andohahela* from original recordings made by F. Andreone: Calls were series of 2-11 notes. Note duration was 263-661 ms (489 ± 85 ms, $n=13$), inter-note interval duration was 377-879 ms (505 ± 156 ms, $n=11$). Each note consisted of 11-19 (14 ± 2 , $n=13$) temporal elements which are here referred to as “pulses”. “Pulse” duration was 8-32 ms (20 ± 4

ms, n=35), inter-“pulse” interval duration was 12-28 ms (17 ± 4 ms, n=32). “Pulse” repetition rate was 24-33/s (29 ± 3 /s, n=13). Note repetition rate was about 1/s. These notes were sometimes preceded by shorter notes of 63-78 ms (n=3). Frequency was 3600-4900 Hz, dominant frequency was 3900-4600 Hz. Generally, a frequency modulation (increasing frequency) was present at the beginning of a note.

These calls were surprisingly similar to those of *Boophis jaegeri* from north-western Madagascar. Re-analysis of recordings from Nosy Be (22 January 1991, 18:30 h, 26 °C air temperature) yielded the following parameters: Note duration 264-577 ms (413 ± 108 ms, n=10), inter-note interval duration 673-3438 ms (1758 ± 1070 ms, n=8), up to 20 “pulses” per note, “pulse” repetition rate 34-38/s, “pulse” duration 12-16 ms (15 ± 2 ms, n=7), inter-“pulse” interval duration 10-14 ms (12 ± 1 ms, n=6). Note series were often succeeded by a “final” short note of three pulses (duration about 85 ms).

Discussion

Our data demonstrate genetic homogeneity in *Boophis ankaratra* along a rather long stretch of the central highlands of Madagascar. Advertisement call recordings were available from all populations studied genetically and similar temporal and spectral call parameters were evident in the recorded specimens. In contrast, *Boophis schuboeae*, showed a relevant genetic and bioacoustic differentiation. This case study therefore provides further support for a gener-

Fig. 5. Distribution map of *Boophis ankaratra* and *B. schuboeae*. Localities of *B. schuboeae* are Ambatolahy and Vohiparara, both in the Ranomafana National Park; localities of *B. ankaratra* are (1) Ambohitantely, (2) Mandraka, (3) Manjakatempo (Ankaratra Massif; type locality), (4) Col des Tapias, (5) Itremo, (6) Andringitra.

al trend in *Boophis*: distinct bioacoustic differences were correlated with high genetic divergence in all pairs or trios of sibling species

Fig. 6. Strict consensus of five equally most parsimonious cladograms obtained by Maximum Parsimony analysis (exhaustive search) of the available sequences (536 nt of the mitochondrial 16S rRNA gene) of *Boophis ankaratra* and *B. schuboeae*. The number above the *B. ankaratra* lineage is a bootstrap value in percent (2000 replications). *B. cf. sibilans* was used as the outgroup.

Fig. 8. Sonagram and oscillogram of a call (one note) of *Boophis jaegeri* from Nosy Be.

studied so far (Vences et al. in press).

Although distinct temporal differences between the calls of *B. schuboeae* and *B. ankaratra* are evident, their general call structure is similar. In contrast, *B. andohahela*, which reminds *B. schuboeae* by the presence of light dorsolateral stripes, has totally different advertisement calls. A molecular analysis (Vences et al. in press) placed *B. schuboeae* with high bootstrap support as sister species of *B. ankaratra*. Although no molecular data on *B. andohahela* are thus far available, we strongly suppose that this species is phylogenetically distant from *B. schuboeae*. It may be closely allied to *B. jaegeri*,

which has very similar advertisement calls; if this hypothesis was confirmed by phylogenetic reconstructions, they would confirm the value of advertisement call structure to infer relationships among closely related species, at least as long as they are not sympatric and bioacoustic characters thus not subject to character displacement.

The presence of similar species as *B. schuboeae* and *B. ankaratra* at different altitude levels is apparently no unusual pattern in Madagascar. However, examples known so far mainly include pairs of sibling species occurring in lowlands versus mid-altitudes: e.g. *Mantidactylus*

redimitus (low-altitude) and *M. cornutus* (mid-altitude), *Mantidactylus aglavei* (low- and mid-altitude) versus *M. finbriatus* (mid-altitude), *Mantidactylus luteus* (low-altitude) versus *M. sculpturatus* (mid-altitude) (Glaw & Vences 1994, 2001, Vences & Glaw 2001). In contrast, only a single example exists so far of siblings from mid-altitudes versus high altitudes: *Mantella baronii* versus *M. cowani* (Vences et al. 1998, 1999). The recognition of *B. schuboeae* as distinct species and as sister species of *B. ankaratra* adds a second example and highlights the presence of frog species in Madagascar characterized by a narrowly delimited elevational endemism. Future studies may show that other species, which currently are believed to have a wide elevational range, are actually complexes of two or more closely related species as well.

Acknowledgements

We are especially grateful to Dr. Anna Schubö and Dr. Werner Schubö, for their generous support of this study. We thank Erica Doumenq, Liliane Raharivoloniaina, Domoina Rakotomalala, Fara Ranavivojaona, and Vanessa Rasuamampianina for their help in the field. Franco Andreone kindly provided recordings of *B. andohahela* for re-analysis, and Denis Vallan allowed analysis of his call recordings of *B. ankaratra* from Ambohitantely. Joachim Kosuch contributed some of the DNA sequences. Both authors were financially supported by the "Deutscher Akademischer Austauschdienst" DAAD. We are indebted to the Malagasy authorities for research and export permits.
