Abstract. *Nisitrus* Saussure, 1878 is a diurnal and monophyletic group of eneopterine crickets found in parts of Southeast Asia. Species often have vivid colourations which make them charismatic photograph subjects among macro photographers. However, their taxonomy has not been revised since their original descriptions, whereas there are also species awaiting to be discovered and described. A synoptic revision is therefore needed prior to studying the phylogenetic relationships of the genus, and before undertaking more precise studies on biogeography and evolution of traits. By holistically incorporating information about general morphology, male and female genitalia, and bioacoustics, we revise the taxonomy of these crickets and recognise 10 valid species of *Nisitrus*. Five new species are described: *N. crucius* Robillard & Tan sp. nov. from Borneo; *N. danum* Robillard & Tan sp. nov. from Borneo; *N. hughtani* Robillard & Tan sp. nov. from Sumatra; *N. malaya* Robillard & Tan sp. nov. from Malay Peninsula; and *N. rindu* Robillard & Tan sp. nov. from Borneo. We redescribe *N. brunnerianus* and *N. insignis*; describe the calls of *N. malaya* sp. nov., *N. musicus* and *N. vittatus*. We consider *N. sumatrensis* as a junior synonym of *N. insignis*; and *N. marginata* as a junior synonym of *N. vittatus*. *Nisitrus hyalinus* requires further revision. We also consider *N. maculosus* as a dubious name.

Keywords. Nisitriini, key, lectotype, redescription, Southeast Asia.

Tan M.K., Wahab R.H.A., Japir R., Chung A.Y.C. & Robillard T. 2021. Revision of the cricket genus *Nisitrus* Saussure (Orthoptera: Gryllidae: Eneopterinae) and descriptions of five new species. *European Journal of Taxonomy* 761: 1–75. <https://doi.org/10.5852/ejt.2021.761.1449>

Introduction

Nisitrus Saussure, 1878 is a monophyletic and morphologically unique group of common eneopterine crickets distributed in Southeast Asia (Fig. 1). It belongs to the tribe Nisitrini Robillard, 2004 along with the apterous genus *Paranisitra* Chopard, 1925, which was taxonomically reviewed in a recent study (Baroga-Barbecho *et al.* 2019). Unlike many eneopterines, *Nisitrus* are slender with long legs, with contrasting vivid colourations (generally black and yellow), with transparent forewings in males, and fully developed hindwings (often with colour patterns) capable of short distance flight. Currently, eight species are known from Borneo, Malay Peninsula and Sumatra, but extinct populations are reported from Java and, probably erroneously, from Maluka (Cigliano *et al.* 2020).

Nisitrus are diurnal, and males can be heard calling among vegetation throughout daytime (Fig. 2). As these crickets usually stay on the foliage, they tend to feed on fresh leaves and flowers (Tan *et al.* 2017). They can be widely distributed and abundant locally (e.g., Tan *et al.* 2012, 2013a, 2015; Tan & Wahab

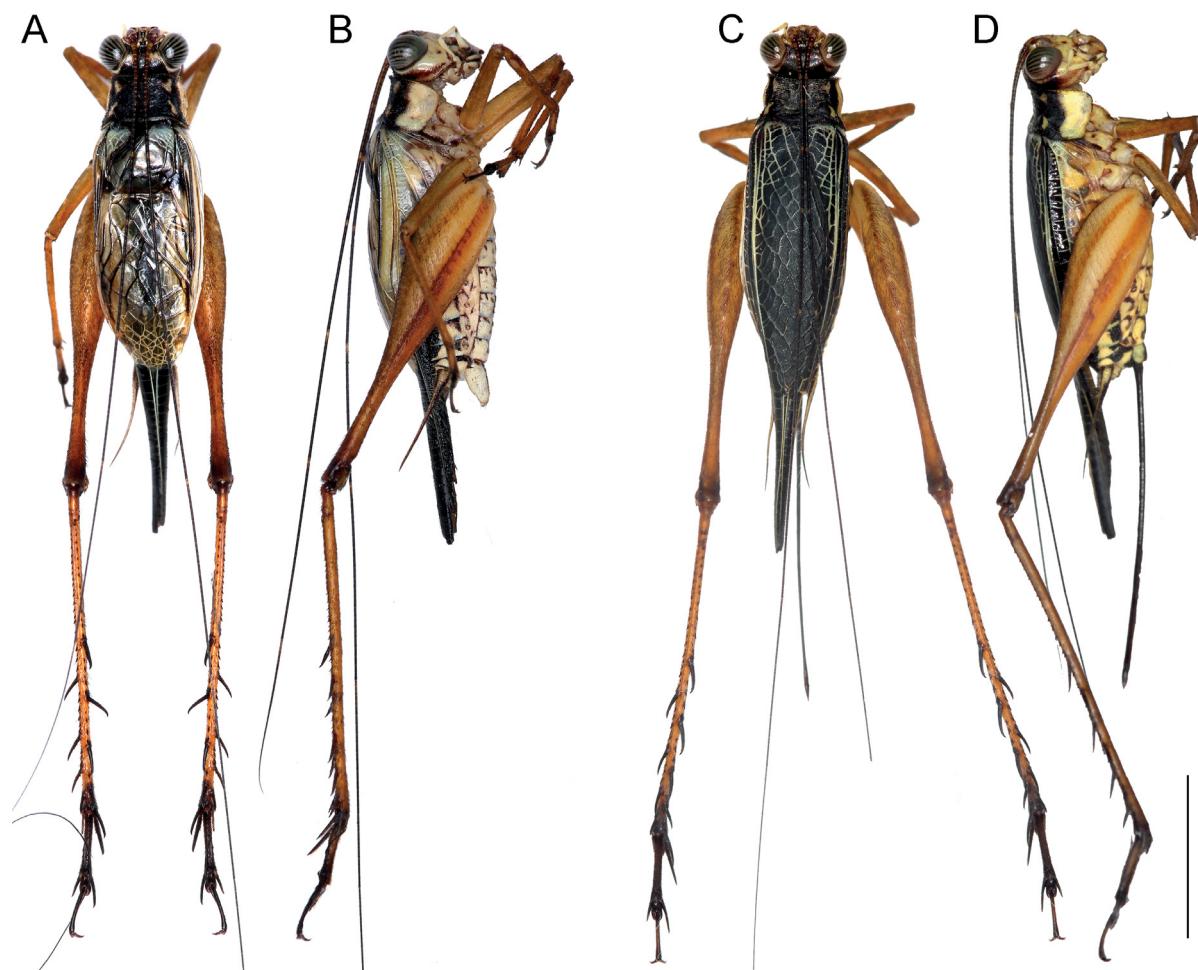

Fig. 1. Habitus of *Nisitrus vittatus* (Haan, 1844) in dorsal (A, C) and lateral (B, D) views. A–B. ♂. C–D. ♀. Scale bar = 5 mm.

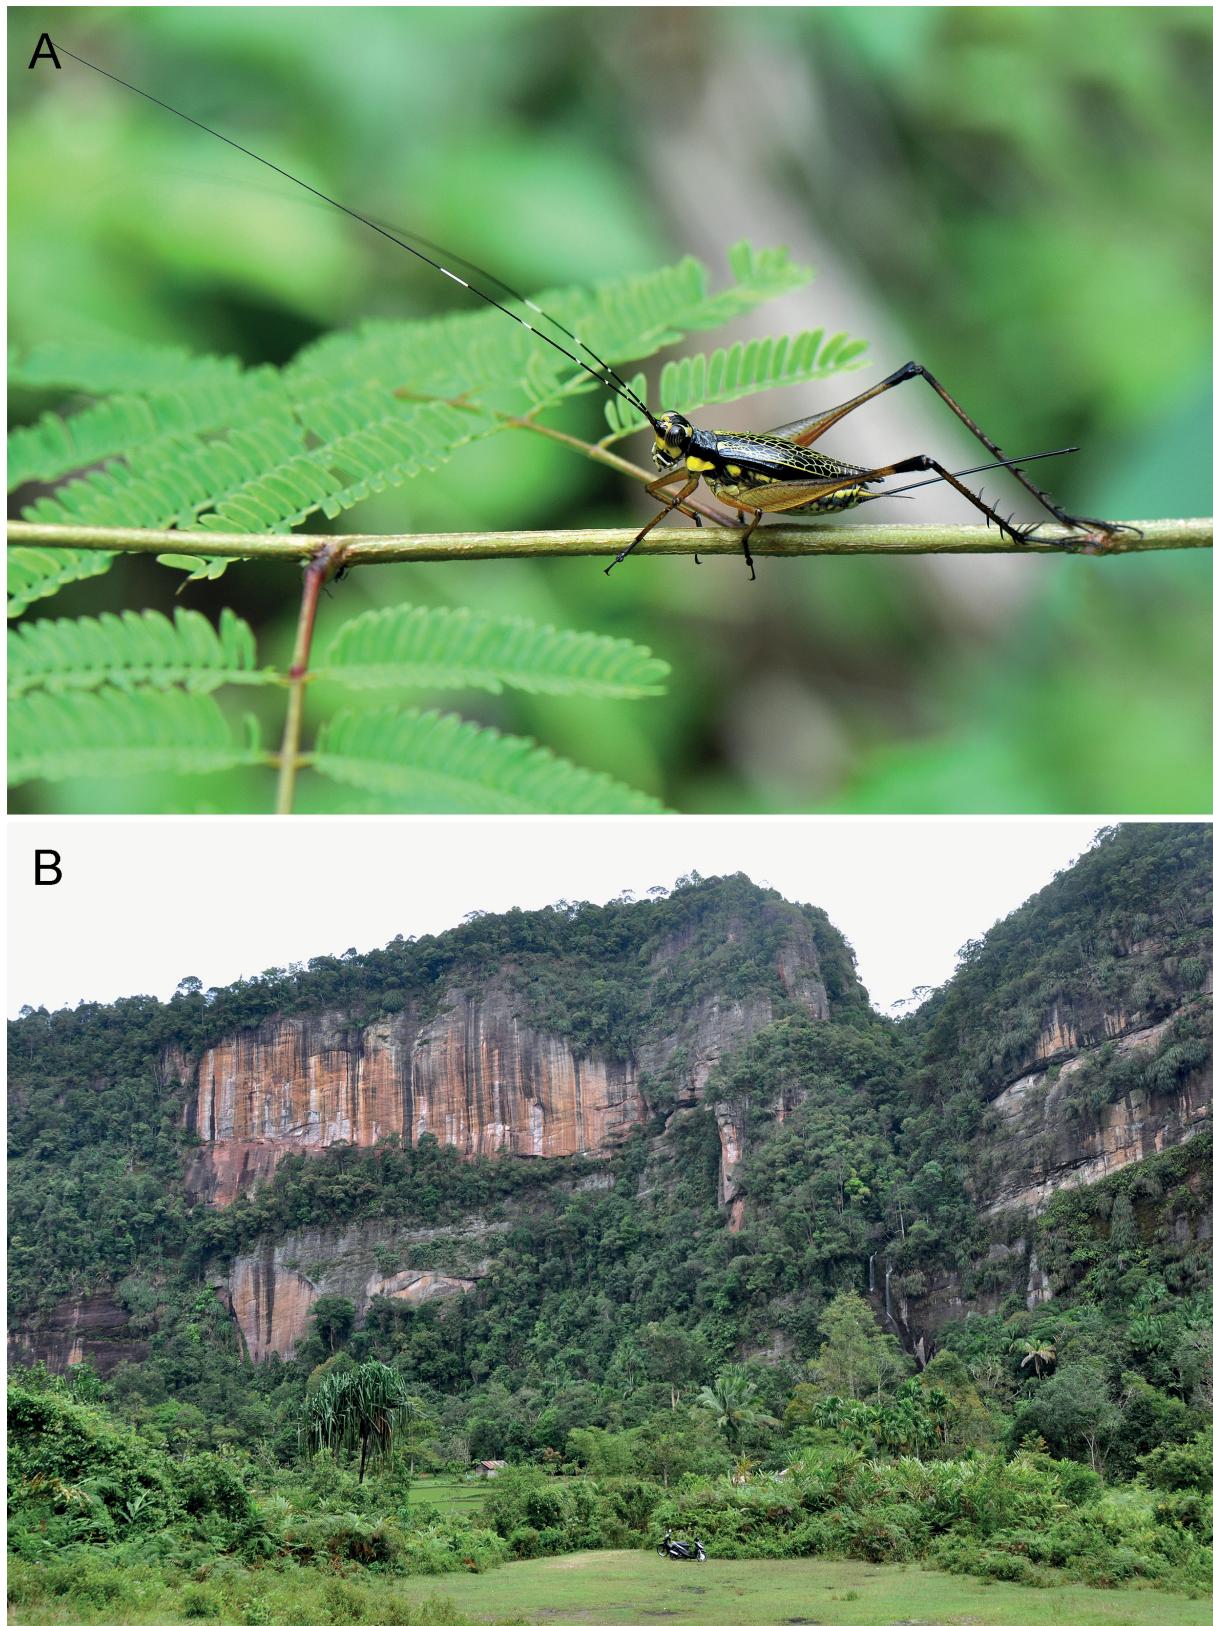

Fig. 2. A. *Nisitrus insignis* Saussure, 1878, adult ♀. B. Natural habitat of a typical *Nisitrus* Saussure, 1878, Lima Puluh Koto, Sumatra, Indonesia. Photograph source and credits: iNaturalist; Dries Nys and Marion Vancauwenbergh.

2018). As such, they can easily be spotted by macro photographers (thanks to their flamboyant nature, bright colouration and diurnal nature) and they make charismatic photograph subjects and are also often observed by citizen science initiative participants such as iNaturalist, where they add up to at least 700 observations from 265 observers (iNaturalist 2020).

In the context of the study of the evolution of communication systems in crickets, the genus is also often used as a representative member of the eneopterine clades that produce low-frequency acoustic signals, by comparison to species producing high frequencies (Robillard *et al.* 2013; ter Hofstede *et al.* 2015; Schneider *et al.* 2017). As such, and due to the facility to breed them in captivity, they are also excellent candidates for detailed studies on the acoustic communication in crickets, even if these studies focus mainly on a single species only.

Such studies are also possible because *Nisitrus* has been recognised as a stable monophyletic group (see Robillard & Desutter-Grandcolas 2006; Vicente *et al.* 2017), having been established to be sister to the clade containing both tribes Xenogryllini Robillard, 2004 and Lebinthini Robillard, 2004 (Vicente *et al.* 2017). While the monophyly of the genus is well supported, the relationships among species of *Nisitrus* are still unclear, since hitherto four species were represented in the phylogenies. More crucially, this is also attributed to the absence of a systematic revision and species clarification for the genus, and to the fact that several species are potentially awaiting discovery.

The taxonomy of these crickets remains problematic, with species delimitation and identification difficult among many species. In this study, we revise their taxonomy using an integrative approach. By amassing a large collection of ca 450 specimens from numerous natural history collections around the world and citizen science observations and photographs, we examine and evaluate characters of both male and female genitalia, general morphology and colour patterns of both adults and juveniles. We also used acoustics of the crickets to help infer species boundaries and we present a map of the distribution of each species and a key to species.

Material and methods

Material

Specimens in MNHN were studied and additional specimens were loaned from AMNH, AMS, BPBM, FRC, GNME, MHN, MNHN, MZB, NHMUK, NMW, RBINS, RMNH, UBDM, ZIN, ZMH, ZMLU and ZRC (see abbreviations below). Finally, part of the specimens studied here correspond to observation data, mostly from iNaturalist website.

Surveys were also conducted by TR in the lowland forests of Singapore in 2009 and 2011. Surveys were conducted by MKT between 2011 and 2019 in the lowland forests of (1) Singapore, (2) Andulau Forest Reserve, Belait and Kuala Belalong, Temburong of Brunei Darussalam; and (3) Sepilok, Sandakan, Sabah, East Malaysia. Opportunistic collection was conducted during daytime. Whenever possible, in-situ images were taken using a Canon EOS 500D digital SLR camera with a compact-macro lens EF 100 mm f/2.8 Macro USM and Canon Macro Twin Lite MT-24EX was used for lighting and flash. The specimens were preserved in absolute analytical-grade ethanol and later pinned and dry-preserved. A single hind leg from each specimen was also preserved in absolute analytic-grade ethanol for future molecular work. Newly collected specimens are deposited in the collections of the FRC, MNHN, UBDM and ZRC.

Morphology

Male tegminal veins and cells follow terminology by Desutter-Grandcolas (2003) and Robillard & Desutter-Grandcolas (2004a) (Fig. 3). Male and female genitalia have been dissected in softened specimens by cutting the membranes between the paraprocts and the subgenital plate, or between the

ovipositor and the subgenital plate respectively; they have been observed after cleaning with cold KOH, and then kept in glycerine. Male genitalia are named according to Desutter (1987), modified in Desutter-Grandcolas (2003) and Robillard & Desutter-Grandcolas (2004a) (Fig. 4). We also provide terminology used by Gorochov (2015) in square brackets. Female genitalia are named according to Robillard & Tan (2013). Abbreviations: see below.

Molecular data

We used a fragment of the mitochondrial gene 12S rRNA gene (12S, amplicon ~400 bp) as a barcoding marker. DNA extraction, PCR amplification, and sequencing for all newly generated sequences were carried out at Service de Systématique moléculaire of the MNHN, following the protocols as described in Dong *et al.* (2018), including primers and annealing temperatures.

Sequences were cleaned and checked for sequencing errors in Sequencher ver. 4.9 (Gene Codes Co.) or Geneious ver. R9.0.2 (Biomatter Ltd., New Zealand, www.geneious.com; Kearse *et al.* 2012), and BioEdit ver. 7.0.5.3 (Hall 1999), then blasted with NCBI blast tools, and submitted to GenBank (Table 1).

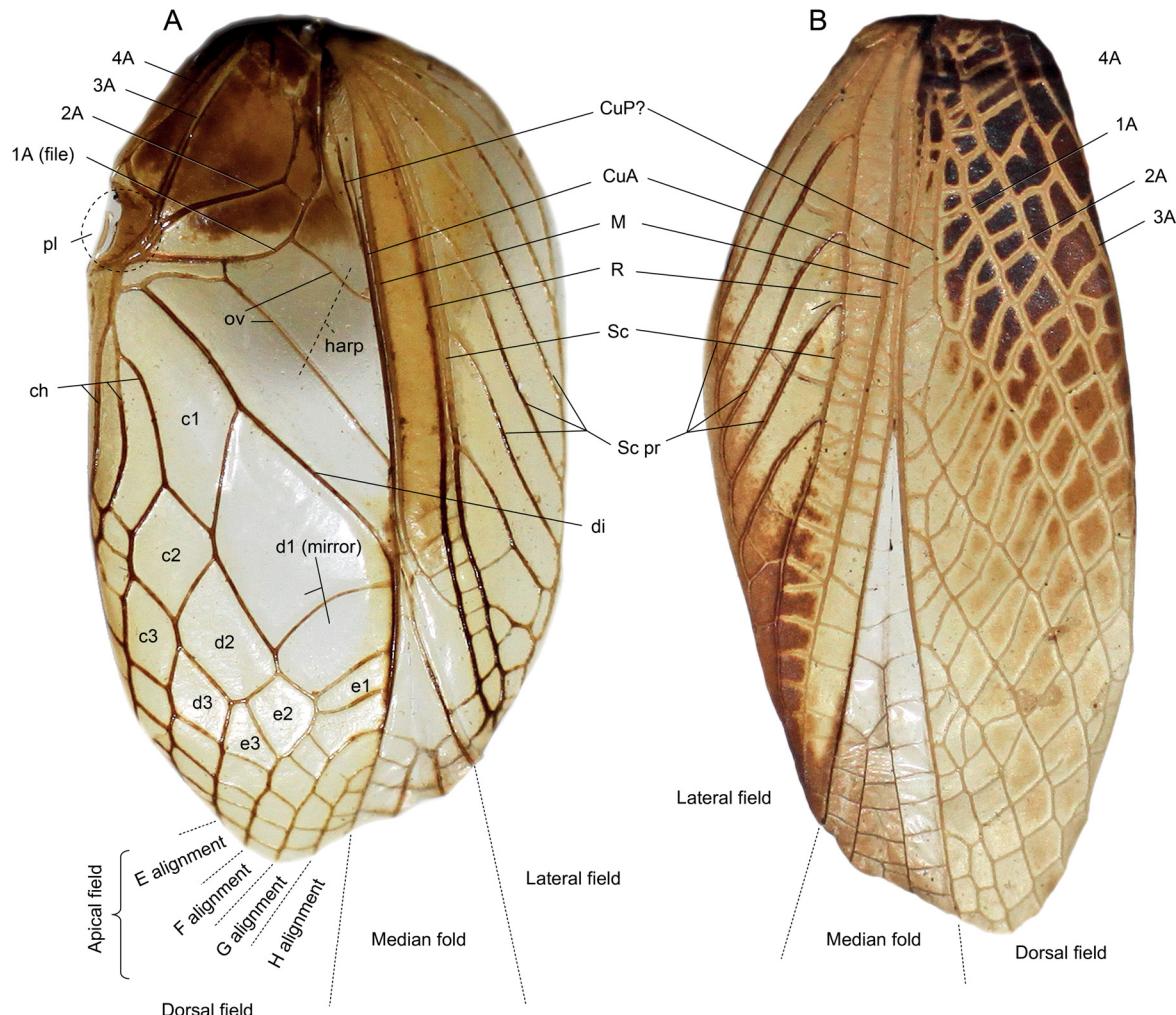

Fig. 3. Forewing venations (with labels of the veins and areas) of *Nisitrus vittatus* (Haan, 1844). **A.** ♂. **B.** ♀. Scale bar = 5 mm.

The sequences were aligned with MAFFT ver. 7 online (Kuraku *et al.* 2013; Katoh *et al.* 2017). The complete combined dataset consisted of 403 aligned base pairs (bp) for a total of 28 terminals, including 3 sequences of the species *Paranisitra longipes* Chopard, 1925 to represent the sister genus *Paranisitra*, and 1 sequence of *Gryllus bimaculatus* De Geer, 1773, used as outgroup in the phylogenetic analysis. Phylogenetic analyses were carried out using the IQ-TREE web server (<http://iqtree.cibiv.univie.ac.at/>; Trifinopoulos *et al.* 2016); maximum likelihood phylogenetic reconstruction was run using IQ-TREE ver. 1.6.2 web portal (Nguyen *et al.* 2015) (<http://iqtree.cibiv.univie.ac.at/>) and ModelFinder (Kalyaanamoorthy 2017). Clade support was assessed by conducting 1000 ultrafast bootstrap replicates (Hoang *et al.* 2017). Branches supported by bootstrap support values (BS) $\geq 70\%$ were considered strongly supported.

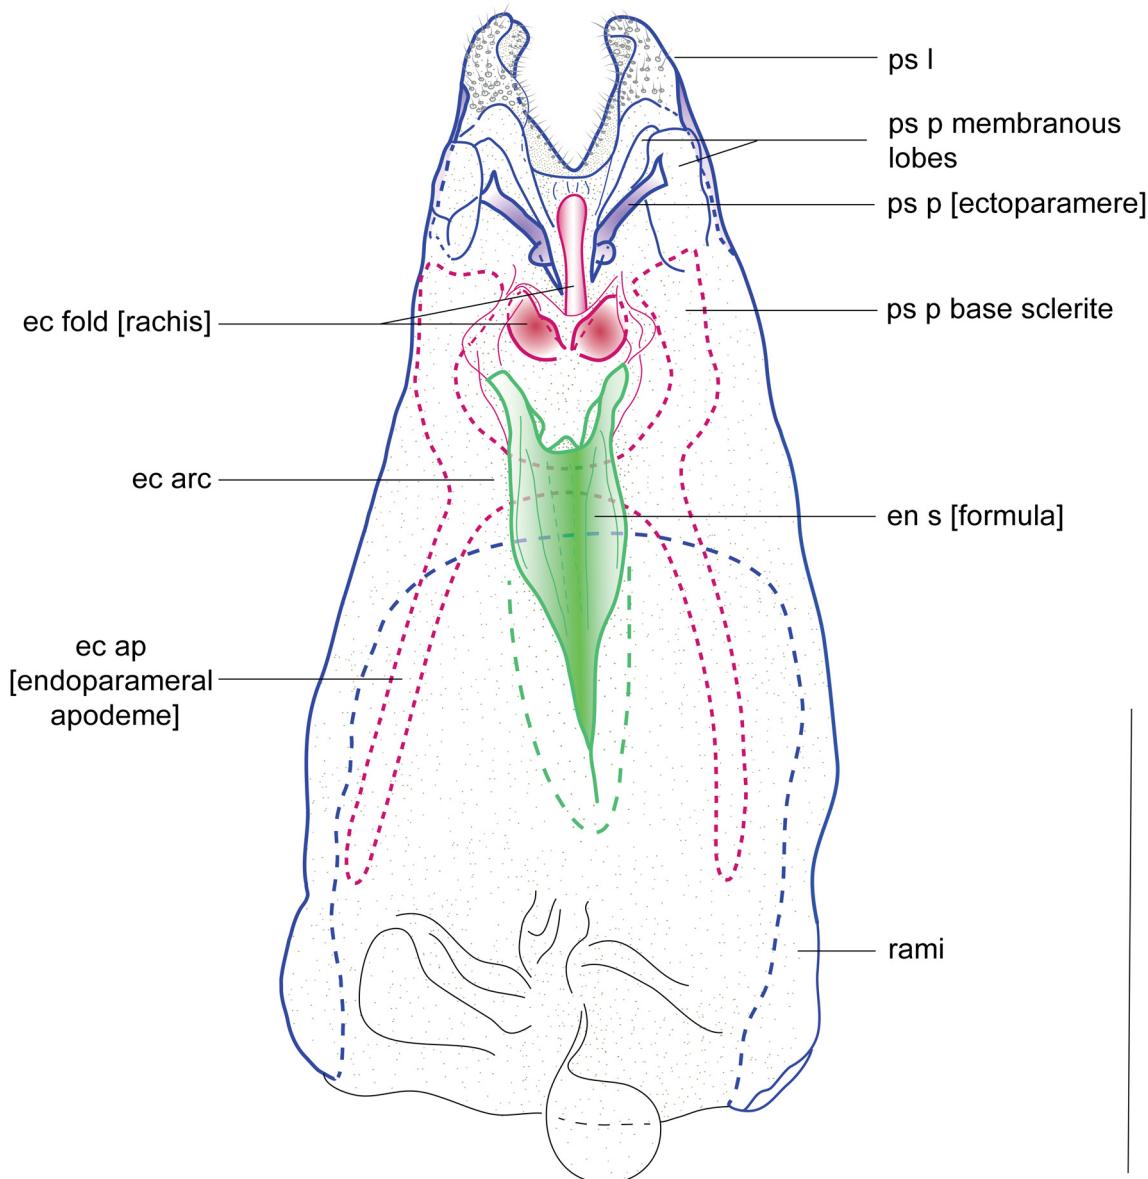

Fig. 4. Drawing of male genitalia of *N. malaya* Robillard & Tan sp. nov. (with labels of parts). Abbreviations: see Material and methods; names of structures follow Desutter (1987), modified after Desutter-Grandcolas (2003) and Robillard & Desutter-Grandcolas (2004a). Terminology used by Gorochov (2015) in square brackets. Scale bar = 1 mm.

Acoustics

The basic cricket song terminology follows Ragge & Reynolds (1998). One song unit is called a syllable and corresponds to one opening-closure cycle of the male forewings.

The calls of three species are described (i.e., *N. malaya* Robillard & Tan sp. nov. and *N. musicus* Ingrisch, 1987) and redescribed (i.e., *N. vittatus* (Haan, 1844)) here having been recorded in the field and/or in the laboratory from specimens collected as juveniles or sub-adults. The recordings were made with a

modified Condenser Microphone Capsule CM16 (Avisoft Bioacoustics, Berlin), with a flat frequency response from 3 to 150 kHz (R. Specht pers. com.), connected to a Tascam HD-P2 digital recorder (96 kHz sampling frequency, 16 bit) in the field, or using Avisoft Triggering Harddisk Recorder ver. 2.97 and an 8-Pre MOTU sound card at a sampling frequency of 96 ksamples/s (16 bit). Song features were measured using Avisoft Lite ver. 2.0.0. Power spectra using Fast Fourier Transformation (FFT) were generated using the ‘meanspec’ function at 256 000 sampling frequency, using a Hanning window of window length 512 from the R package ‘seewave’ (Sueur *et al.* 2008). All recording files are deposited in the Sound Library of the MNHN under accession numbers MNHN-SO-2020-2851 to MNHN-SO-2020-2860.

To examine how the call properties of *N. malaya* sp. nov., *N. musicus* and *N. vittatus* differ, the call properties (which were not mutually independent and likely to be highly intercorrelated) were summarised into major gradients of variation by performing a Principal Coordinates Analysis (PCoA) on the scaled call properties using the ‘cmdscale’ function in R ver. 3.5.1 (R Development Core Team 2018). The nine call properties are: echeme duration, echeme period, downtime between consecutive echemes, first to third syllable durations, fundamental frequency, frequencies of the second and third harmonics. Gower dissimilarity was used as it can be calculated for a set of descriptors containing continuous values bounded by zero.

Georeferencing of specimen labels

The description of the localities was manually georeferenced using Google Earth Pro to obtain GPS coordinates. Too imprecise localities were excluded (e.g., only Borneo, Sumatra). Dubious localities were also excluded. For specimens collected during the Midden Oost Borneo Expeditie 1925 in Kalimantan, we georeferenced the localities provided on the map in the book (Buys *et al.* 1927) (Supp. file 1).

Results

Five new species of *Nisitrus* (Orthoptera Latreille, 1793: Gryllidae Laicharting, 1781: Eneopterinae Saussure, 1874) are described: *N. crucius* Robillard & Tan sp. nov. from Borneo; *N. danum* Robillard & Tan sp. nov. from Borneo; *N. hughtani* Robillard & Tan sp. nov. from Sumatra; *N. malaya* Robillard & Tan sp. nov. from Malay Peninsula and *N. rindu* Robillard & Tan sp. nov. from Borneo (Table 2). We consider *N. sumatrensis* (Rehn, 1909) as a junior synonym of *N. insignis* Saussure, 1878; and *N. marginatus* (Walker, 1869) as a junior synonym of *N. vittatus* (Table 1). We also consider *N. maculosus* (Walker, 1871) as a dubious name (Table 2). In total, we recognise 10 species of *Nisitrus*: *N. brunnerianus* Saussure, 1878, *N. crucius* sp. nov., *N. danum* sp. nov., *N. hughtani* sp. nov., *N. hyalinus* Saussure, 1878, *N. insignis*, *N. malaya* sp. nov., *N. musicus*, *N. rindu* sp. nov. and *N. vittatus* (Table 2). The distribution of the nine valid species (excluding *N. hyalinus*) in Southeast Asia is also presented in Fig. 5.

The maximum likelihood tree resulting from the phylogenetic analysis of the mitochondrial gene 12S rRNA marker yielded a largely robust topology within the clade of six species of *Nisitrus* (Fig. 6). Within *Nisitrus* clade, all species were recovered as monophyletic with high support values, supporting the species delimited by morphology. *Nisitrus musicus*, *N. brunnerianus* and *N. hughtani* sp. nov. form a well-supported clade (BS of 93.7%), sister to the clade comprising *N. vittatus* and *N. malaya* sp. nov. (BS of 93.8%). Specimens of *N. vittatus* and *N. malaya* sp. nov. form distinct and well supported clades (BS of 93.4% and 73.4%, respectively), despite their similarity in adult morphology.

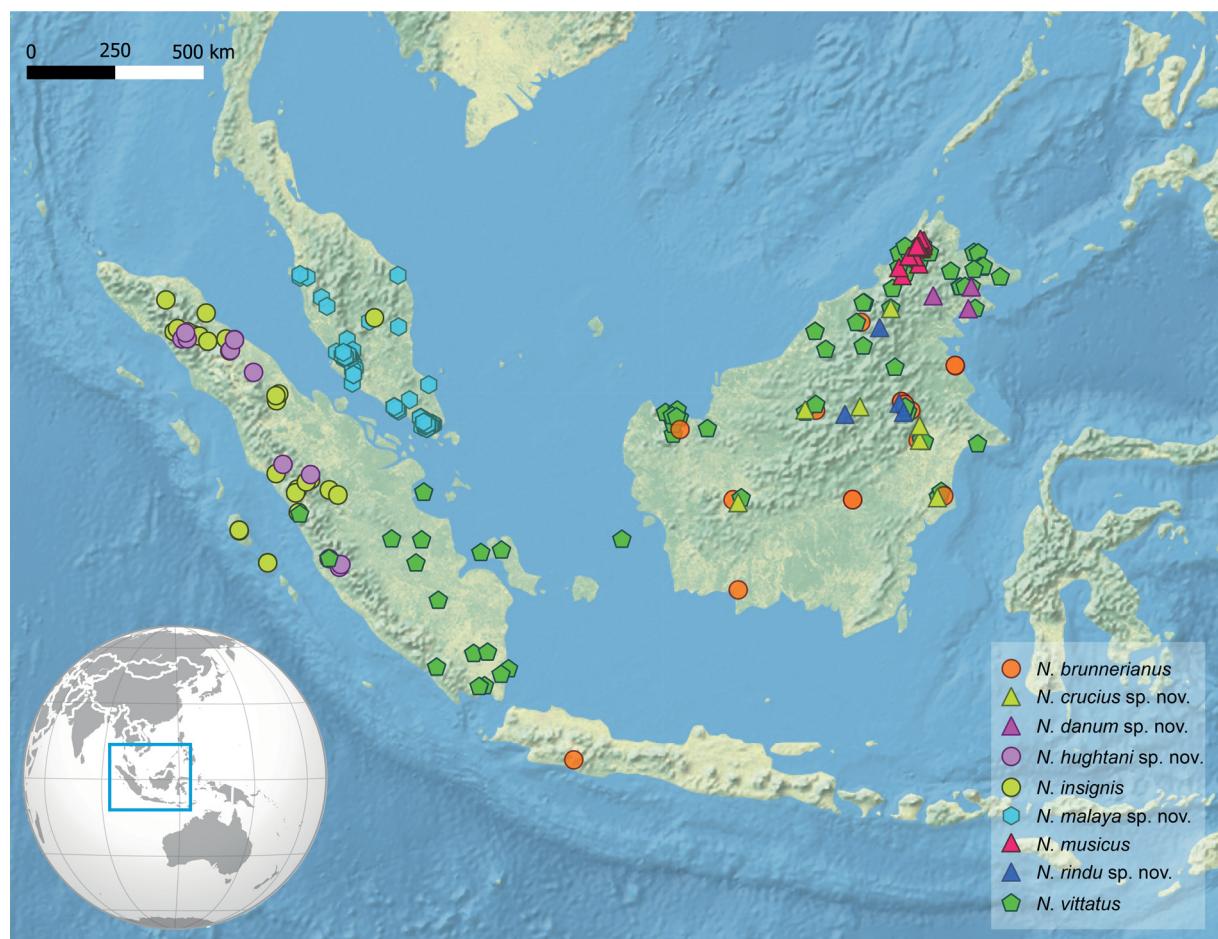

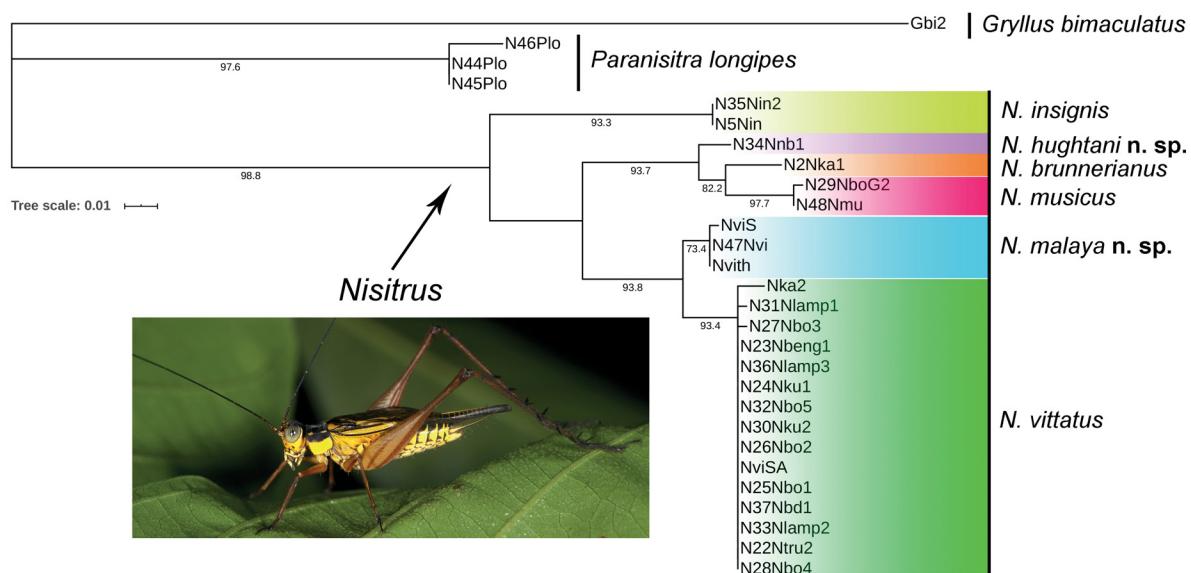

Fig. 5. Map of Southeast Asia showing the distribution of species of *Nisitrus* Saussure, 1878. Each coloured symbol represents one sampling or observation locality listed in the material in the text.

Table 2. Status of original species epithets associated with *Nisitrus* Saussure, 1878.

Original epithet	Original author and year	Status
<i>brunnerianus</i>	Saussure, 1878	valid (redescribed)
<i>crucius</i>	Robillard & Tan sp. nov.	valid, new species
<i>danum</i>	Robillard & Tan sp. nov.	valid, new species
<i>hughtani</i>	Robillard & Tan sp. nov.	valid, new species
<i>hyalinus</i>	Saussure, 1878	valid, needs further revision
<i>insignis</i>	Saussure, 1878	valid
<i>maculosa, maculosus</i>	Walker, 1871	nomen dubium (new status)
<i>malaya</i>	Robillard & Tan sp. nov.	valid, new species
<i>marginata, marginatus</i>	Walker, 1869	synonym of <i>vittatus</i> (new status)
<i>musicus</i>	Ingrisch, 1987	valid
<i>rindu</i>	Robillard & Tan sp. nov.	valid, new species
<i>sumatrensis</i>	Rehn, 1909	synonym of <i>insignis</i> (new status)
<i>vittata, vittatus</i>	Haan, 1844	valid

Genus *Nisitrus* Saussure, 1878

Nisitra Walker, 1869: 91.

Nisitra – Chopard 1940: 199.

Nisitrus – Saussure 1878: 511, 522 (nomen novum for *Nisitra* Walker). — Chopard 1968: 352. — Desutter-Grandcolas 1990: 239. — Otte 1994: 67. — Preston-Mafham 2000: 2241 (behaviour). — Robillard & Desutter-Grandcolas 2004a: 276; 2004b: 578; 2004c: 304; 2006: 644; 2008: 67 (Nisitrini tribe); 2011: 637. — Robillard *et al.* 2007: 1265. — Desutter-Grandcolas *et al.* 2010: 616. — Nattier *et al.* 2011: 2201 (phylogeny and molecular dating). — Robillard & Tan 2013: 707 (redescription and diagnosis). — Vicente *et al.* 2017: 2203 (phylogeny, historical biogeography). — Cigliano *et al.* 2020 (Orthoptera Species File Online).

Type species

Nisitra vittatus (Haan, 1844).

Remarks on type species

Kirby (1906) and Chopard (1968) listed *N. vittata* as the type species of *Nisitra* and treated the original type species *N. marginata* Walker, 1869 as a synonym of *N. vittata*. Subsequent authors listed *N. vittatus* as the type species of the replacement name *Nisitrus*, although Otte (1994) reinstated *N. marginatus* as a valid species (Braun 2013 in Cigliano *et al.* 2020). The present revision revalidates the synonymy of *N. marginatus* under *N. vittatus*, making *N. vittatus* the valid type species of the genus.

Diagnosis (emended from Robillard & Tan 2013)

Among genera of Eneopterinae, *Nisitrus* is characterised by an elegant, wasp-like, slender and colourful body (Figs 7–9). Size average for subfamily. Colouration vivid, dominantly yellow, whitish and black, with species-specific patterns, particularly in the head (Figs 10–11), pronotum (Figs 11–12) and FWs (Figs 12–14). Characteristic head shape with narrow fastigium and large prominent eyes with thin dorso-ventral black stripes. Pronotum setose, square-shaped to slightly trapezoidal, usually bisinuated posteriorly. Metanotum with large glandular structures in males, made of a wide pit on scutum and a pair of posterior pits on scutellum, with glandular pores mostly organised by groups of 2 or 3 (Fig. 15). FWs more or less as long as abdomen. Male *Nisitrus* show modified FW venation and characteristic glossy transparency. Hindwings longer than FWs, bicoloured in most species, their base transparent with a wide dark posterior margin. Legs long and thin, FIII with a characteristic narrowed area before knee. Other general traits: TI with two tympana, inner one slit-like, covered by a swollen cuticular expansion; outer tympanum oval, its membrane transversally plicate in dorsal half. TI with three apical spurs; outer dorsal spur missing. TII with four apical spurs, inner longest. TIII with three inner and three outer apical spurs, median longest on each side; four pairs of subapical spurs, inner and outer spurs almost straight, their apex hook-like; TIII serrulate over whole length, slightly furrowed dorsally. Tarsomeres III-1 with one row of dorsal spines on external edge in addition to apical spines. Apical claws of legs slightly indented. Both males and females show characteristic genitalia.

Fig. 7. Scale bar = 2 mm.

Male genitalia (Fig. 16) with membranous and setose lophi well individualised; pseudopiphillic parameres including two membranous posterior lobes and a sclerotized anterior lobe oriented anteriorly toward median axis of genitalia and carrying a secondary preapical sclerotized lobe; ectophallic arc transverse, incomplete due to a little-sclerotized median area; ectophallic fold narrowed preapically, its apex narrow, located between anterior apex of pseudopiphillic parameres; dorsal part of fold sclerotized, forming two elongated sclerites connected to the median area of arc; ventral part of ectophallic fold membranous, with two strong rounded lateral sclerites of variable shapes. Membrane of endophallic cavity smooth. Female copulatory papilla (Fig. 17) conical, apex generally sclerotized and pointed. Ovipositor typically longer than FIII; apex thin with both dorsal and ventral edges smooth.

Phylogenetic relationships

Based on previous phylogenetic studies (Robillard & Desutter-Grandcolas 2004c; Nattier *et al.* 2011; Vicente *et al.* 2017), *Nisitrus* is the sister genus of *Paranisitra* Chopard, 1925 (revision in Gorochov 2009 and Baroga-Barbecho *et al.* 2019). The two genera form the Nisitrini tribe (Robillard & Desutter-Grandcolas 2008) and are very close morphologically; *Paranisitra* is mostly characterised by a lack of wings in both sexes, but except for this, it shares with *Nisitrus* its general body shape, long thin legs with indented claws, colouration with yellow and black, head shape with large prominent eyes and narrow fastigium, and the general structure of male and female genitalia. Nisitrini are less easy to relate to other clades of Eneopterinae.

Natural history

Species tend to be found at forest edges and gaps in the forest where the vegetation is more exposed. They are also found among shrubs and herbaceous plants (but not grasses). *Nisitrus* are observed to be generally diurnal, during which the males can be heard calling and individuals are found foraging in the vegetation. It seems as *Nisitrus* are mostly herbivorous, feeding on leaves, but also on flowers (Tan *et al.* 2017). *Nisitrus* are also observed to congregate with one another on the same plant, sometimes making up of more than 20 individuals of both adults and nymphs. They can be considered a pest in some parts of Southeast Asia (Willemse 2001).

Included species

Nisitrus brunnerianus from Borneo and Java; *N. crucius* sp. nov. and *N. danum* sp. nov. (both from Borneo); *N. hughtani* sp. nov. from Sumatra; *N. hyalinus* from Borneo; *N. insignis* from Sumatra and Malay Peninsula; *N. malaya* sp. nov. from Malay Peninsula; *N. musicus* and *N. rindu* sp. nov. from Borneo; and *N. vittatus* from Sumatra and Borneo.

Distribution

Borneo (Sabah and Sarawak States of East Malaysia, Brunei Darussalam, and Kalimantan State of Indonesia), Java, Malay Peninsula (Peninsular Malaysia and Singapore) and Sumatra (Indonesia) (Fig. 5).

Key to the species of *Nisitrus* Saussure, 1878

1. Frons mostly black, or with large dark markings (e.g., cross-shaped pattern); gena usually black, although may have yellow band ventral of eye 2
- Frons mostly yellow, sometimes with small dots but without large dark markings; gena usually yellow 5
2. FW with longitudinal white stripe around region of CuA, M and R with a distinct margin from black colouration on dorsal field; lateral field usually infumated black ventrally. Distribution: Sumatra *N. hughtani* Robillard & Tan sp. nov.
- FW with longitudinal white stripe around region of CuA, M and R darkens progressively towards the dorsal field without a distinct margin from black colouration on dorsal field; lateral field usually light coloured or transparent ventrally. Distribution: Borneo and Java 3
3. Smaller in size, female FWL typically <11.3 mm. Frons with a characteristic black cross marking *N. crucius* Robillard & Tan sp. nov.
- Larger in size, female FWL typically >11.8 mm. Frons completely black; without a characteristic black cross marking 4
4. Dorsum of head completely black. Pronotal lateral lobe either with ventral half yellow or with an oval yellow spot at the anterior end *N. brunnerianus* Saussure, 1878
- Dorsum of head pale with some dark markings. Pronotal lateral lobe with a characteristic dorsal yellow band that extends ventrally *N. rindu* Robillard & Tan sp. nov.
5. Frons with black band between eyes, mouthparts mostly yellow. Body darker; female FW typically with infumated black cells, with lateral parts of dorsal field usually with an infumated yellow longitudinal stripe. Distribution: Borneo (Sabah) *N. danum* Robillard & Tan sp. nov.
- Frons without black band between eyes, mouthparts black. Body usually with more yellow colouration; male FW with some black and white infumation, but generally transparent. Distribution: Borneo, Malay Peninsula and Sumatra 6
6. Legs usually pale in colouration; FIII with at least one black longitudinal stripe on external face. Male FW with distinct infumated white spots and infumated black pattern near base, sometimes with infumated white patterns around chords, but otherwise transparent, harp very small, with one distinct straight oblique vein; female FW almost always with yellow/white veins. Distribution: Sumatra *N. insignis* Saussure, 1878
- Legs usually brown in colouration; FIII with faint or without black longitudinal stripe on external face. Male FW with infumated black pattern near base, sometimes with infumated white spots, but otherwise transparent, harp larger, with 3 oblique veins; female FW sometimes with yellow/white veins. Distribution: Sumatra, Borneo, Malay Peninsula 7
7. Eyes dark when alive. Frons yellow, face part of fastigium (including scapes) and mouthparts black, maxillary palpi yellow; dorsal part of legs black. Male pseudopiphallus slender. Distribution: Borneo, near Kinabalu area *N. musicus* Ingrisch, 1987
- Eyes green when alive. Frons yellow to brown, mouthparts sometimes yellow or brown; legs typically homogenous brown. Pseudopiphallus more robust, broad. Distribution: Sumatra, Borneo, Malay Peninsula 8

8. Lighter in colouration. Lateral field of FWs usually light in colouration. Juveniles of pale white colouration with numerous dark stripes all around the body. Female copulatory papilla without truncated lobule at the ventro-anterior end. Distribution: Borneo, Sumatra
..... *N. vittatus* (Haan, 1844)

– Darker in colouration. Lateral field of FWs usually dark in colouration. Juveniles of darker colouration, usually grey, their pronotum without longitudinal stripes but dorsal disk sometimes with a large velvety black spot. Female copulatory papilla with a truncated lobule at the ventro-anterior end. Distribution: Malay Peninsula *N. malaya* Robillard & Tan sp. nov.

Diagnosis

This species differs from all known congeners by the following characters: head nearly completely black (sometimes with yellow patch beneath scapes and eyes). Pronotum lateral lobe either black with small brown spot on postero-ventral corner, or black in dorsal half and yellow in ventral half. Male FW with basal area brown with tint of black, otherwise mostly hyaline; veins mostly yellow. Female FW with dorsal field mostly infumated black, with veins dark brown and lighten towards lateral field and apical areas. Legs red brown; FIII black dorso-basally without bands or stripes on external surface; with a distinct black ring before hind knee; hind knee black. Abdomen with tergites black, sternites mostly black. This species is similar to *N. crucius* sp. nov. and *N. rindu* sp. nov. but differs by the combination of these characters: frons nearly completely black (without black cross marking as in *N. crucius* sp. nov.), dorsum of head completely black (vs with yellow margins in *N. crucius* sp. nov. or pale with dark patterns in *N. rindu* sp. nov.) and lateral lobe either with ventral half yellow or with an oval yellow spot at the anterior end (vs with a characteristic dorsal yellow band that extends ventrally in *N. rindu* sp. nov.).

Redescription

Relatively large and slender (Figs 7A, 18). Vertex completely black (Fig. 11A). Fastigium velvety black, with anterior margins yellow. Scapes black, posterior end red brown. Antennae red brown with some segments black and with wide whitish rings. Eyes dark green when alive and red brown when dried. Frons generally black, sometimes with yellow to cream-coloured bands above and beneath antennal cavity and along ventral margins of eyes (Fig. 10A). Mouthparts dark red brown to black. Maxillary palpi cream-coloured; apical segment black apically (Fig. 10A). Head lateral side black (Fig. 12A). Pronotum generally black, covered with white setae; dorsal disk trapezoidal, posterior margin bisinuated (Fig. 11A). Lateral lobes of pronotum with two variants: (1) in lectotype, completely black except for a cream-coloured oblong spot near anterior margin (Fig. 12A); (2) dorsal third black, otherwise completely yellow. Legs red brown. FIIIs dark red brown, sometimes with a dorsal black longitudinal stripe; knees dark brown to black; TIIIs brown with black spines and spurs, dark brown to black near distal end; tarsomeres dark brown to black. Hindwings hyaline brown, with a rounded transparent window near internal-basal area; longer than FWs, the dark brown tail exceeding FWs more than twice as long as pronotum. Tergites black, in some segments with cream-coloured transverse stripe at anterior end and/or with pale band laterally; sternites pale, their median area red brown. Cerci cream-coloured, short and conical.

Male

FOREWINGS. FW colouration (Fig. 13A): dorsal field cells mostly transparent to pale yellow, veins mostly dark brown to black. Basal area brown with tint of black. R brown, Sc projections brown basally, transparent apically. Lateral field yellow brown, apex more transparent. FW venation (Fig. 13A): 1A somewhat straight. Harp slightly longer than wide, with 3 oblique veins, posterior-most vein bifurcated at base. c1 long and wide, c2 diamond-shaped; mirror (d1) longer than wide, not rounded, generally separated into two parts by a distinct, roundly bent transverse vein, the posterior part hexagonal, shorter than anterior part. Cell d2 narrower than d1. Apical field short and rounded, with 2 wide cell alignments

posterior to mirror and a narrow apical alignment; veins yellow. Lateral field with 5–6 projections of Sc. Epiproct black. Subgenital plate pale cream, its median area and anterior and posterior margins black.

GENITALIA (Fig. 16A). Pseudepiphalus sclerotized, relatively large and broad compared to congeners, anterior margin somewhat broad and straight, posterior margin also straight, lateral margins faintly converging posteriorly. Posterior apex with paired lophi longer than wide (at base), subacute at apex, sclerotized laterally only and covered with strong short setae; spaced apart from one another. Rami swollen preapically, anterior apex somewhat truncated. Pseudepiphalic parameres narrow, divergent posteriorly, their basis membranous, with a sclerotized lobe on anterior apex. Ectophallic arc transverse, complete, with anterior and posterior margins straight. Ectophallic fold strong rounded lateral sclerites appearing bean-shaped. Ectophallic apodemes long and thin, straight and slightly divergent basally. Endophallic sclerite large and sclerotized, its posterior apex with divergent lateral arms and with a short median expansion curved dorsally. Endophallic apodeme with lateral lamellae stout.

Female

FOREWINGS. FW colouration (Fig. 14A): cells on dorsal field mostly infumated black, gradually becoming yellow near CuA, M and R veins; veins generally black or dark brown, also gradually becoming yellow towards CuA, M and R veins; veins near apical area also yellow. Sc projections cream-coloured basally, black apically. Lateral field dark. FW venation: 6–7 strong longitudinal veins on dorsal field, sometimes not smooth; lateral field with 6 projections of Sc.

Figs 5, 7B, 8C, 10B, 11B, 12B, 13B, 14B, 16B, 17C–D; Tables 2, 4

Diagnosis

This species differs from all known congeners by the following combination of characters: frons yellow, with a cross-shaped black pattern above mouthparts; face part of fastigium between eyes black. Male FWs with a basal area generally paler; female ovipositor only about as long as FIII. *Nisitrus crucius* sp. nov. is similar to *N. brunnerianus*, from which it differs by smaller size and shorter ovipositor. It is also similar in size to *N. vittatus* and *N. malaya* sp. nov. but differs by female FW with cells on dorsal field mostly infumated black, gradually becoming yellow near CuA, M and R veins.

Etymology

The species name refers to the dark cross marking on the frons ('*crucis*' = 'cross', in Latin).

Description

Average size (Fig. 7B). Colour pattern somewhat intermediate between *N. brunnerianus* and *N. vittatus*. Vertex black with cream-coloured margin around eyes (Fig. 11B). Fastigium velvety black with cream-coloured margins. Scapes black dorsally, sometimes reddish ventrally or along dorso-inner margins. Antennae black. Frons yellow, face part of fastigium black between eyes, with a cross-shaped black pattern above mouthparts; clypeus sometimes darkened, mouthparts dark red brown to black (Fig. 10B). Maxillary palpi cream-coloured. Head lateral side generally black. Pronotal disk black with white setae (Fig. 11B). Lateral lobes of pronotum with dorsal third black, cream-coloured ventrally (Fig. 12B). Legs red brown, sometimes internal-basal area black. FIIIs dark red brown, knees dark brown to black; TIIIs brown with black spines and spurs, dark brown to black near distal end; tarsomeres dark brown to black. Hindwings dark hyaline, with a rounded transparent window near internal-basal area; longer than FWs, the dark brown tail exceeding the FWs about twice as long as pronotum. Tergites black, with a pale band laterally of variable thickness; sternites pale, with a black median area.

Male

FOREWINGS. FW colouration (Fig. 13B): dorsal field cells mostly transparent; veins mostly cream-coloured, sometimes black. Basal area brown, basally cream-coloured, brown towards distal part. R and Sc projections cream-coloured. Lateral field hyaline, with dorsal parts infumated cream-coloured. FW venation (Fig. 13B): 1A somewhat straight. Harp slightly longer than wide, with 2 oblique veins, distal one bifurcate basally. Cell c1 long and wide, c2 diamond-shaped; mirror (d1) longer than wide, not rounded, generally separated into two parts by a distinct straight transverse vein, the posterior part somewhat rectangular, much shorter than anterior part. Cell d2 narrower than d1, usually subdivided by accessory veins. Apical field short and rounded, with 3 wide cell alignments posterior to mirror and a narrow apical alignment; veins cream-coloured. Lateral field with 5 projections of Sc. Epiproct black. Subgenital plate pale cream-coloured with median area and anterior and posterior margins black.

GENITALIA (Fig. 16B). Pseudepiphalus sclerotized, stout (small but broad) compared to congeners, anterior margin somewhat broad and straight, posterior margin also straight, lateral margins faintly converging posteriorly. Posterior apex with paired lophi slightly longer than wide (at base), obtuse at apex, sclerotized laterally only and covered with short strong setae; narrowly spaced apart from one another. Rami swollen preapically, anterior apex somewhat truncated. Pseudepiphalic parameres narrow, divergent posteriorly, their basis membranous, with a sclerotized lobe on anterior apex. Ectophallic arc transverse, complete, with anterior and posterior margins straight. Ectophallic fold strong rounded lateral sclerites appearing bean-shaped. Ectophallic apodemes long, straight and slightly divergent basally. Endophallic sclerite large and sclerotized, its posterior apex with divergent lateral arms and with a short median expansion curved dorsally. Endophallic apodeme with lateral lamellae stout.

Female

FOREWINGS. FW with cells on dorsal field mostly infumated black, gradually becoming yellow near CuA, M and R veins; veins generally yellow (Fig. 14B). Sc projections cream-coloured. Lateral field transparent, sometimes infumated black apically.

GENITALIA. Ovipositor: only slightly longer than FIII. Copulatory papilla conical, smaller and stout; apex folded ventrally, short, pointed; dorsal face with a sclerotized area; ventro-anterior end forming an oval to pyriform rim (Fig. 17C–D).

Juvenile

Unknown.

Figs 5, 8D, 10C, 11C, 12C, 14C, 17E, 19; Tables 2, 5

Diagnosis

This new species differs from all known congeners by face part of fastigium with a black band across eyes and antennal cavity, frons otherwise yellow (reddish on preserved specimens); pronotal lateral lobe black dorsally and yellow ventrally; longitudinal white stripe only between M and R and lateral field matted black; Sc projections black. This new species is most similar to *N. hughtani* sp. nov. from Sumatra, but differs by the following characters: smaller in size, vertex black with yellow margin around eyes (instead of cream-coloured), frons with a black band across eyes and antennal cavity (yellow in *N. hughtani* sp. nov.); frons yellow (instead of black with a cream-coloured band ventral to eyes); mouthparts yellowish with some black spots; lateral part of head with a black band posterior of eye (instead of black with a cream-coloured ring around eye). This species is also similar to *N. musicus* from Kinabalu range, but differs by mouthparts yellow (instead of black), FIIIs not black dorsally, female papilla, and distribution: *N. musicus* is restricted to the highlands in the Kinabalu range, while *N. danum* sp. nov. occurs in the Danum Valley and Tawau Hill areas at the east of Sabah.

Etymology

The specific name is a noun in apposition taken from the type locality, Danum Valley, Malaysia.

Material examined

Holotype

MALAYSIA – **Sabah** • ♀; Danum Valley Field Centre; 4°57'52.95" N, 117°48'18.25" E; ca 150 m a.s.l.; 26 May–20 Jun. 1987; C. v. Achterberg and Kennedy leg.; PII: N54; RMNH.

Paratypes

Description

Slender and relatively large habitus (Figs 8D, 19). Vertex black with yellow margin around eyes (Fig. 11C). Fastigium velvety black with yellow margins. Scapes dark red brown to black (particularly on the dorso-inner margins). Antennae black with wide whitish rings. Face part of fastigium with a black band across eyes and antennal cavity, otherwise yellow (reddish in preserved specimens); frons almost entirely yellow, including mouthparts, with some black spots (Fig. 10C). Maxillary palpi cream-coloured; apical segment black apically (Fig. 10C). Lateral part of head with a black band posterior to eye (Fig. 12C). Pronotum

covered with white setae; dorsal disk dark brown to black (Fig. 11C). Lateral lobes of pronotum dorsal third black, vivid yellow ventrally (cream-coloured in preserved specimens) (Fig. 12C). Legs generally red brown, sometimes dorsally darker. FIIIs brown, knees dark brown to black; TIIIs brown with black spines and spurs, dark brown to black near distal end; tarsomeres dark brown to black. Tergites red brown, with a pale band laterally; sternites pale, with red brown median area. Cerci red brown, short and conical.

Male

Unknown.

urn:lsid:zoobank.org:act:8E5BC124-4F3C-432E-BB94-A19C32128B06

Figs 5, 7C, 8E, 10D, 11D, 12D, 13C, 14D, 15A, 16C, 17F–G, 20; Tables 1–2, 6

Diagnosis

Large and slender species. Head mostly black, but with cream-coloured margin around eyes in both dorsal and lateral views; frons mostly black, but yellow ventral to eyes and antennal cavity; maxillary palpi white. Pronotum dorsal lobe black, lateral lobe mostly white or yellow, its dorsal margin black. Female

FWs with dorsal field infumated black; lateral field ventrally black; M/R area forming a clearly defined white/yellow stripe. This species is most similar to *N. danum* sp. nov. from Borneo, but differs by the following characters: larger in size, vertex black with cream-coloured margin around eyes (instead of yellow); frons and mouthparts dark red brown to black; frons black with a cream-coloured band ventral to eyes (instead of completely yellow). This species also differs from the sympatric *N. insignis* by frons mostly black (instead of yellow); lateral field M/R area forming a clearly defined white stripe (instead of dark); female FW dorsal field with veins black (instead of yellow) and juvenile colouration.

Etymology

The new species is named after Prof. Hugh Tiang Wah Tan, a renowned botanist and conservation biologist from Singapore and the PhD supervisor of M.K. Tan.

Description

Habitus large and slender, colouration very contrasting with black, white and vivid yellow when alive (Figs 7C, 20A–B). Vertex black with cream-coloured margin around eyes (Fig. 11D). Fastigium velvety

Fig. 20. *Nisitrus hughtani* Robillard & Tan sp. nov. in its natural environment in West Sumatra. A–B. Adult ♀♀. C–E. Juveniles. Photograph source and credits: iNaturalist; Oscar Johnson (A), Michael Kesl (B–E).

black with cream-coloured margins. Scapes dark red brown to black (particularly on the dorso-inner margins). Antennae black with wide white rings. Frons and mouthparts dark red brown to black, frons cream-coloured (whitish when alive) ventral to eyes (Fig. 10D). Maxillary palpi cream-coloured; apical segment black apically (Fig. 10D). Head lateral side dark coloured, with broad cream-coloured band around eyes extending to area behind eyes (Fig. 12D). Pronotum covered with white setae; dorsal disk velvety black (Fig. 11D). Lateral lobes of pronotum with dorsal-third black, cream-coloured ventrally, vivid yellow when alive (Fig. 12D). Legs dark brown. FIII brown, knees dark brown to black; TIIIs brown with black spines and spurs, dark brown to black near distal end; tarsomeres dark brown to black. Hindwings hyaline brown apically, longer than FWs, the dark brown tail exceeding FW more than twice as long as pronotum. Tergites red brown, with a pale band laterally; sternites pale, with a red brown median area. Cerci red brown.

Male

FOREWINGS. FW colouration (Fig. 13C): dorsal field cells mostly transparent, veins mostly dark brown to black, cream-coloured in apical field. Basal area brown, basally cream-coloured, brown towards distal part. R cream-coloured, Sc projections cream-coloured basally, black apically. Lateral field brown. FW venation (Fig. 13C): 1A curved, slightly angulated. Harp slightly longer than wide, with 3 oblique veins, basal one bifurcate distally, distal one bifurcate basally. c1 long and wide, c2 diamond-shaped; mirror (d1) longer than wide, not rounded, generally separated into two parts by a distinct transverse vein, the posterior part hexagonal, shorter than anterior part. Cell d2 narrower than d1, more or less rectangular. Apical field short and rounded, with 3 wide cell alignments posterior to mirror and a narrow apical alignment. Lateral field with 6 projections of Sc. Epiproct black. Subgenital plate pale cream-coloured with median area, anterior and posterior margins black.

GENITALIA (Fig. 16C). Pseudepiphalus sclerotized, large and slender, anterior margin narrow and straight, posterior margin also straight, lateral margins distinctly converging posteriorly. Posterior apex with paired lophi longer than wide (at base), subacute at apex, sclerotized laterally only and covered with short strong setae, narrowly spaced apart from each other. Rami swollen preapically, somewhat sinuous. Pseudepiphalllic parameres narrow, divergent posteriorly sclerotized arm base to parameres distinctly curved laterally. Ectophallic arc transverse, complete, with anterior and posterior margins straight. Ectophallic fold strong rounded lateral sclerites appearing bean-shaped. Ectophallic apodemes long, straight and slightly divergent. Endophallic sclerite large and sclerotized, its posterior apex with divergent lateral arms and with a short median expansion curved dorsally. Endophallic apodeme with lateral lamellae and dorsal crest only slightly longer than wide.

Female

FOREWINGS. FW colouration (Fig. 14D): cells black, veins generally black. Longitudinal white stripe around region of CuA, M and R with a distinct margin against black colouration on dorsal field; Sc projections cream-coloured basally, black apically. Lateral field dark. FW venation: 6–7 strong longitudinal veins on dorsal field; lateral field with 6 projections of Sc.

GENITALIA. Ovipositor: distinctly longer than FIII. Copulatory papilla conical, large (similar to *N. brunnerianus* but less slender—possibly due to preservation of specimen); apex folded ventrally, elongated like in *N. brunnerianus*, pointed; dorsal face with a sclerotized area, but less sclerotized than in congeners; ventro-anterior end forming a somewhat triangular rim (Fig. 17F–G).

Juvenile (Fig. 20C–E)

Early instars with a pale colouration with numerous dark stripes all around body. Head generally reddish. Eyes with numerous dark stripes. Pronotum with three thick, dark longitudinal stripes on dorsal disk, one very thick and velvety black stripe between dorsal disk and lateral lobe; another curved stripe on lateral

Nisitrus hyalinus Saussure, 1878

Fig. 21; Table 2

Nisitrus hyalinus Saussure, 1878: 516.

Nisitrus hyalinus — Chopard 1968: 353. — Hollier *et al.* 2013: 487 (no types in MHNG). — Cigliano *et al.* 2020 (Orthoptera Species File online).

Nisitra hyalina — Kirby 1906: 87. — Chopard 1969: 313.

non *Nisitrus hyalinus* — Chopard 1929: 110 (record in Siberut may be *N. insignis*). — Robillard & Desutter-Grandcolas 2004a: 276 (morphological phylogeny).

Type locality

Borneo: Kalimantan, “Benjermassing” [Banjarmasin].

Type details

Syntypes, RMNH (missing).

Remarks

The syntypes in RMNH are missing. L. Chopard’s records (Chopard 1929) of this species in Mentawai, North Pagi, Siberut and Padang (all part of or related to Sumatra, Indonesia) correspond to specimens of *N. insignis*, while *N. hyalinus* is known only from Borneo. We cannot revise this species owing to the absence of type material and of other specimens from the region of the type locality in the south of Borneo. Nonetheless, we have found images of specimens from Sungai Utik, Embaloh Hulu, Kapuas Hulu Regency, West Kalimantan, albeit not exactly near the type locality in Banjarmasin in South Kalimantan, which could possibly correspond to *N. hyalinus*. These photographs (Fig. 21) match the description by Saussure (1878): “*Les élytres latéralement hyalins dans leur partie marginale, d’un noir opaque luisant dans leur partie médiastino-humérale; le champ dorsal brunâtre, réticulé en jaune par mailles plus grandes que chez le N. vittatus. Ailes assez courtes, hyalines, nébuleuses, surtout le long du limbe. Fémurs postérieurs très longs; leur moitié apicale linéaire, comme chez le N. insignis*”. [The elytra laterally hyaline in their marginal part, a shiny opaque black in their medial-humeral part; the dorsal field brownish, reticulated in yellow with larger meshes than in *N. vittatus*. Wings rather short, hyaline, nebulous, especially along the limbus. Very long FIII; their apical half linear, as in *N. insignis*.]

We can also confirm that none of the Bornean specimens examined in this study match the description of *N. hyalinus*. Saussure (1878) repeatedly compared *N. hyalinus* with *N. vittatus*, but not with other Bornean species which differ distinctly from *N. vittatus* (i.e., *N. brunnerianus*). *Nisitrus danum* sp. nov. differs

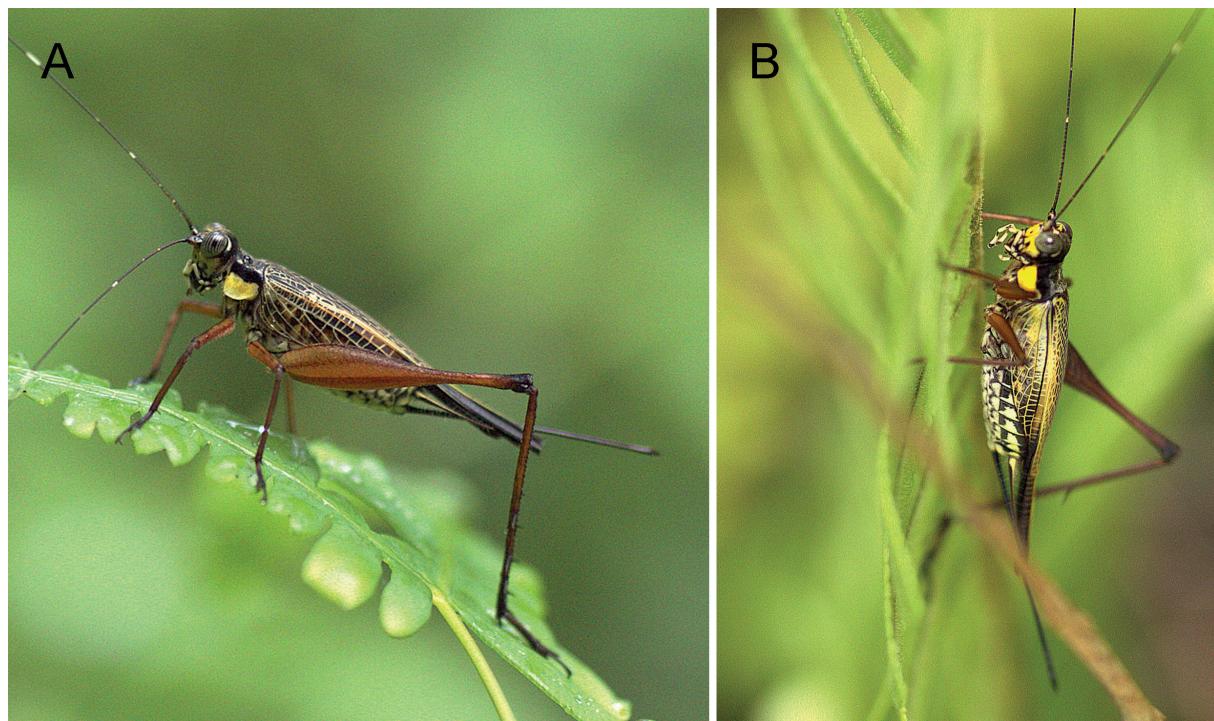

Fig. 21. *Nisitrus hyalinus?*, adult ♀♀ in their natural environment. Photograph source and credits: Marcel Silvius.

from *N. hyalinus* by dorsal field clearly not brownish; lateral field humeral stripe whitish, not shining black; lateral field is not hyaline either. Furthermore, the type locality of *N. hyalinus* from Banjarmasin in southern Kalimantan is quite far from Danum Valley and of a different forest type (Danum Valley is lowland forest, whereas Banjarmasin would have been peat swamp forest). *Nisitrus rindu* sp. nov. also differs by medial-humeral part not shining black opaque. Given the fact that very few specimens of *Nisitrus* are known from Southern Borneo, it is likely that *N. hyalinus* is a valid species but rarely collected.

Nisitrus sp. – Preston-Mahfam 2000: 1 (mating behaviour).

Diagnosis

Of smaller size but stouter habitus than congeners. Vertex coloration ranging from black with cream-coloured margins around eyes and fastigium to cream-coloured with a strong longitudinal black band and one or two faint transverse black band (forming a T- or a cross-shaped black pattern). FIIIs brown, with a brown longitudinal stripe along external ventral half; sometimes dorsal margin with a paler longitudinal stripe. Dorsal field of male FW always with cream-coloured triangular (sometimes rounded) patch, with very distinctly different venation; harp very small, slightly longer than wide, with one distinct straight oblique vein. This species is similar to *N. malaya* sp. nov. and *N. vittatus* but differs by legs with lighter colouration and dorsum of head yellow with variable black pattern (instead of entirely black). This species also differs from the sympatric *N. hughtani* sp. nov. by smaller size, frons yellow (black in *N. hughtani* sp. nov.) and vertex colouration pattern; FW lateral field M/R area dark (instead of forming a clearly defined white/yellow stripe), and female FW dorsal field with veins yellow (instead of mostly black).

MALAYSIA • 4 ♀♀; “Camp Jor”, border between Perak and Pahang; 4°9'43" N, 102°22'20" E; 30 Dec. 1902; Alb. Grubauer leg.; ZMH.

Redescription

Slightly smaller than other species (Fig. 7D). Vivid yellow, brown and black when alive (Fig. 22A–C). Vertex variable: ranging from black with yellow margins around eyes (mostly in individuals from Sumatra) to cream-coloured with a strong longitudinal black band and one or two faint transverse black bands (forming a T- or cross-shaped black pattern; mostly in individuals from Siberut Islands and Malaysia) (Fig. 11E); dark pattern variable between individuals, some have a narrow pattern appearing more like a longitudinal band. Scapes red brown to black. Antennae red brown (individuals from Siberut) to black (individuals from Sumatra), with wide whitish rings. Frons yellow, cream-coloured to yellow, face part of fastigium brown to dark brown or black between eyes, lighter for individuals from Siberut than from Sumatra (Fig. 10E). Mouthparts dark brown to black in specimens from Sumatra, lighter or sometimes yellow in specimens from Siberut (Fig. 10E). Maxillary palpi cream-coloured; apical segment black apically (Fig. 10E). Head lateral side yellow to cream-coloured, including gena, with a black band posterior to eyes (Fig. 12E). Pronotum dorsal disk black, covered with white setae, rectangular with lateral margin barely widening posteriorly, posterior margin substraight to faintly bisinuous (Fig. 11E). Lateral lobes of pronotum dorsal half black, vivid yellow ventrally (cream-coloured in preserved specimens) (Fig. 12E). Legs generally light grey brown, sometimes with some small dark spots. FIIIs brown, with a brown longitudinal stripe along ventral half (more distinct and darker in individuals from Sumatra); sometimes dorsal margin with a paler longitudinal stripe; knees dark brown to black. TIIIs brown with black spines and spurs, dark brown to black near distal end; tarsomeres dark brown to black. Hindwings hyaline brown apically; longer than FWs and surpassing cerci, forming a black tail with yellow veins exceeding FWs for less than twice the length of the pronotum. Tergites red brown, with a pale band laterally; sternites pale, sometimes with a dark brown median area. Subgenital plate with a dark median area.

Male

FOREWINGS. FW colouration (Fig. 13D): dorsal field narrow, cells mostly transparent, veins varying from pale yellow to black. Basal area either infumated brown to black (individuals from Sumatra) or almost transparent (individuals from Siberut), but always with a cream-coloured triangular patch (sometimes more rounded). Chords most often with a white patch, most readily observed in individuals from Sumatra. R black, Sc projections black basally, cream-coloured or transparent apically. Lateral field transparent. FW venation (Fig. 13D): 1A curved, slightly angulated. Harp very small, slightly longer than wide, with one distinct straight oblique vein. c1 long and wide, broader basally; c2 diamond-shaped; mirror (d1) small, longer than wide, not rounded, generally separated into two parts by a transverse vein, the anterior part triangular, about as long as posterior part, posterior part rectangular. Cell d2 about as wide as d1, usually subdivided by accessory veins. Apical field short, including one cell alignment posterior to mirror and a narrow apical alignment; its veins cream-coloured. Lateral field transparent, with 5 or 6 projections of Sc. Epiproct black. Subgenital plate with a dark median area. Cerci red brown.

GENITALIA (Fig. 16D). Pseudoeipiphallus sclerotized, stout (medium-sized but broad) compared to congeners, anterior margin somewhat broad and straight, posterior margin also straight, lateral margins faintly converging posteriorly. Posterior apex with paired lophi slightly longer than wide (at base), obtuse at apex, moderately spaced apart from one another. Rami swollen preapically, anterior apex somewhat truncated. Pseudoeipiphallus parameres narrow. Ectophallic fold rounded lateral sclerites appearing bean-shaped to rectangular. Endophallic sclerite wide and rounded laterally, with relatively long lateral arms.

Female

FOREWINGS. FW colouration (Fig. 14E): base of dorsal field with a yellow area; cells black, veins mostly vivid yellow (cream-coloured in preserved specimens). Region of CuA, M and R black, including the

veins. Sc projections yellow basally, black apically. Lateral field transparent. FW venation: 6–7 strong longitudinal veins on dorsal field; lateral field with 6 projections of Sc.

GENITALIA. Ovipositor slightly longer than FIII. Copulatory papilla conical, smaller and stout; apex folded ventrally, stout, broader than congeners, pointed; dorsal face with a sclerotized area, forming a somewhat triangular rim (Fig. 17H–I).

Females (n = 5)	13–15 (14)	2–5	19–20 (20)	2–5	2	15.7–17.7 (16.7)		

Juvenile (Fig. 22D–E)

Young instar with head nearly completely cream-coloured. Pronotum disk velvety black, lateral lobe with dorsal half velvety black and ventral half cream-coloured. Legs generally cream-coloured with small dark spots; tarsi darker. Abdomen with tergites velvety black dorsally, with sternites cream-coloured ventrally. Epiproct cream-coloured. Later instar resembles adult colouration.

Measurements

See Table 7.

Ecology

Habitat and mating behaviour, including multiple mating, male guarding behaviour, female eating spermatophores and male-male competition for females, were described in detail by Preston-Mahfam (2000).

Distribution

Sumatra, Malay Peninsula (Malaysia).

Type locality

Indonesia: Sumatra.

Calling song

Unknown.

Remarks

One syntype of Saussure from Northern Sumatra found in NMW is designated here as the lectotype of the species. Based on comparisons with the type of *N. sumatrensis*, the latter name is considered as a junior synonym of *N. insignis* (new synonymy, see below).

The observed specimen series vary greatly in size and colouration, which made us hesitate between defining one or more species, in particular for the lighter specimens from the Mentawai Islands. To remain conservative, we considered these differences as species variation only, but more information about molecular divergence and acoustic parameters may lead to revise this decision in future studies.

Diagnosis

Average size, colouration contrasting with black and yellow, characterised by black vertex, yellow frons and orange brown legs. This new species is very close to *N. vittatus* from which it differs by adult and juvenile colouration, male and female genitalia and calling song. General colouration darker, particularly among FW cells and veins beneath R; R black (instead of cream-coloured as in *N. vittatus*); in male venation, anal-most and middle chords narrow and nearly parallel with one another (instead of diverging apically), and basal-most chord extend from basal half of middle chord (instead of at/after midpoint). It differs from *N. vittatus* by the male genitalia with pseudopiphallus more robust, broad, anterior margin more strongly concave. Female copulatory papilla with truncated lobule at the ventro-anterior end. Juvenile differs strikingly in the body colour pattern. Male calling song also differs by longer echeme period. This species is also similar to *N. crucius* sp. nov. in size and habitus, but differs by the absence of cross-shaped black pattern on frons and does not occur in Borneo.

Etymology

This specific name is a noun in apposition referring to the species' distribution in the Malay Peninsula (including Singapore and Peninsular Malaysia).

Description

Habitus similar to *N. vittatus* (Figs 7E, 23A–D): vertex black with cream-coloured margin around eyes (Fig. 11F). Fastigium velvety black with cream-coloured margins. Scapes dark red brown to black (particularly on dorso-inner margins). Antennae black with wide whitish rings. Frons and mouthparts most often yellow with a few dark spots (Fig. 10F). Maxillary palpi cream-coloured, apical segment black apically. Head lateral side yellow, with a wide black band posterior to eye (Fig. 12F). Pronotum covered with white setae; dorsal disk dark red brown to black (Fig. 11F); lateral lobes of pronotum dorsal third black, vivid yellow ventrally (cream-coloured in preserved specimens) (Fig. 12F). Legs dark orange brown. FIIIs brown, knees dark brown to black; TIIIs brown with black spines and spurs, dark brown to black near distal end; tarsomeres dark brown to black. Hindwings hyaline brown apically, transparent basally; longer than FWs, forming a dark brown tail exceeding FWs for more than twice the length of pronotum. Tergites red brown, with a pale band laterally; sternites pale, with a red brown median area. Cerci red brown, lighter dorsally.

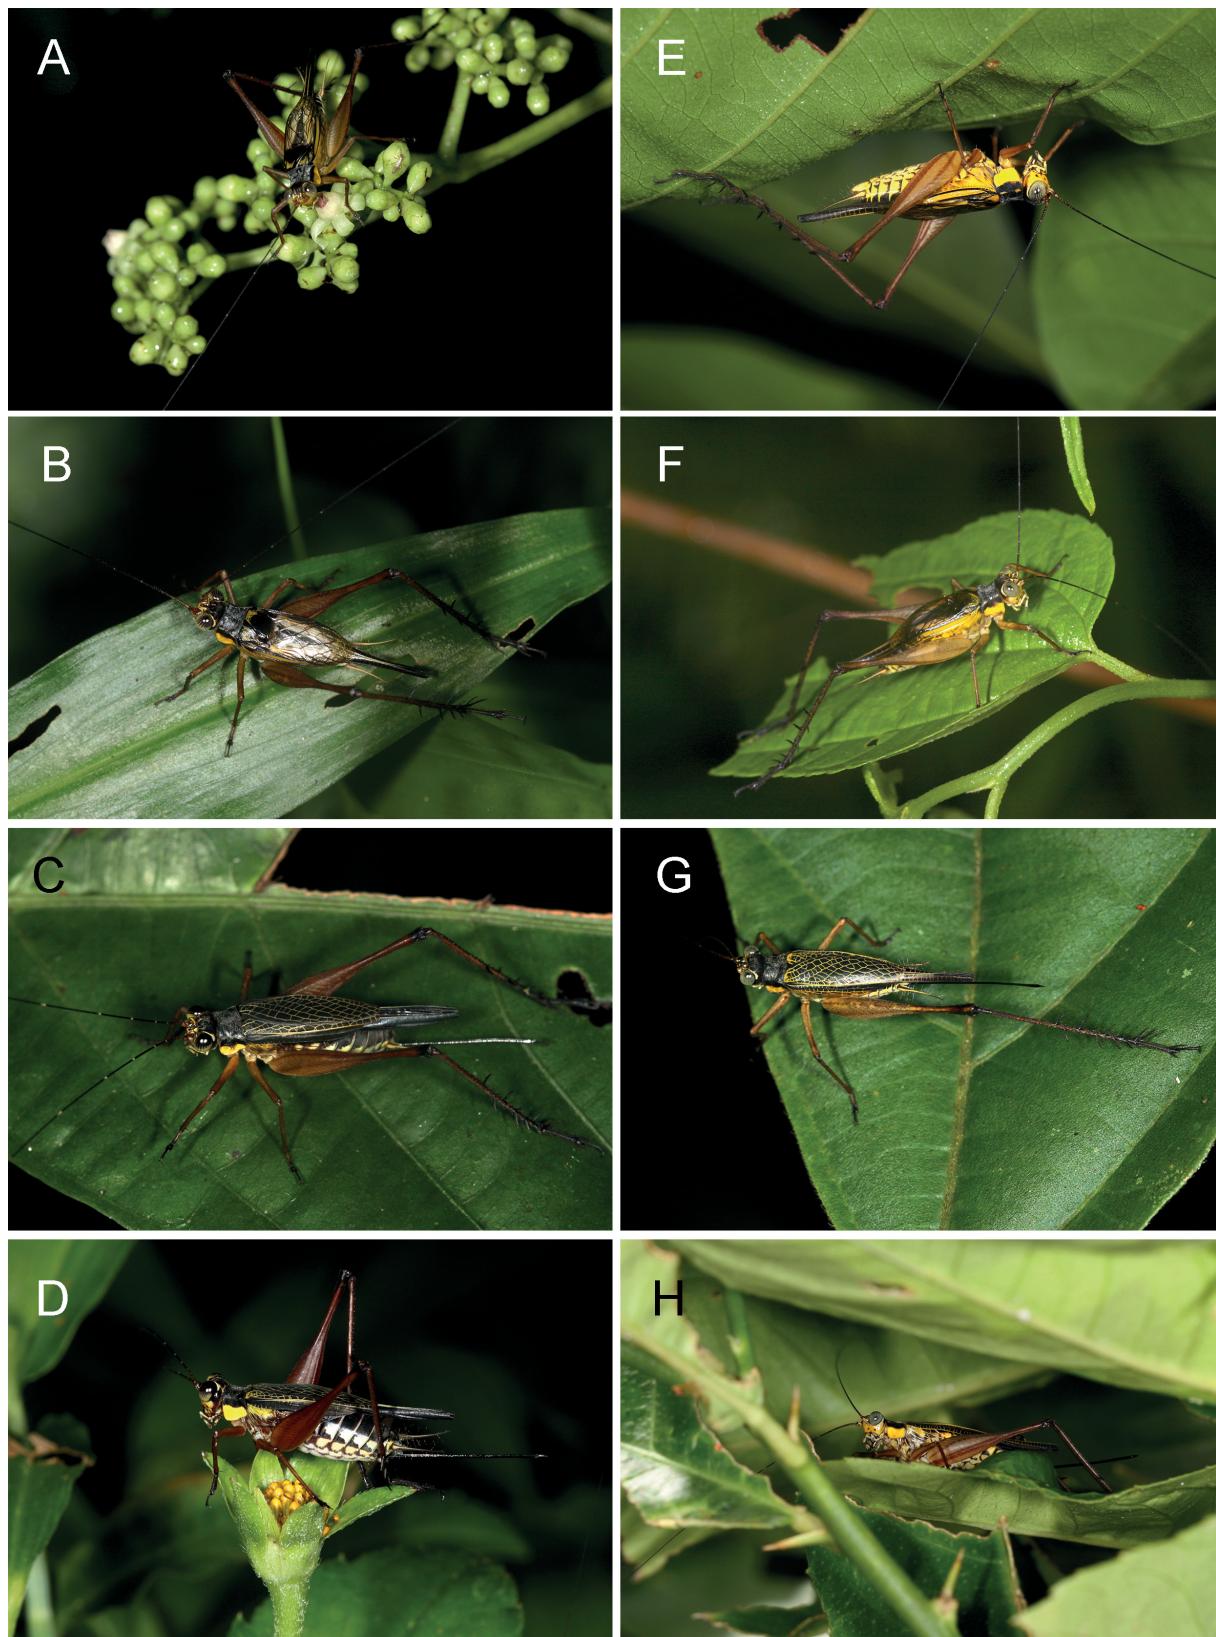

Fig. 23. A–D. *Nisitrus malaya* Robillard & Tan sp. nov. E–H. *N. vittatus* (Haan, 1844). Adult ♂♂ (A–B, E–F) and ♀♀ (C–D, G–H) in their natural environment. Photograph credit: Ming Kai Tan.

Male

FOREWINGS. FW colouration (Fig. 13E): dorsal field cells mostly transparent, veins mostly dark brown to black. Basal FW area black (instead of cream-coloured or brown as in *N. vittatus*), with a relatively small cream-coloured patch basally. R black (instead of cream-coloured as in *N. vittatus*), Sc projections cream-coloured basally, black apically. Apex of dorsal field somewhat truncated. Lateral field dark. FW venation (Fig. 13E): 1A curved, slightly angulated. Harp slightly longer than wide, with 3 oblique veins, basal one bifurcated distally, distal one bifurcated basally. c1 long and wide, c2 diamond-shaped; mirror (d1) longer than wide, not rounded, generally separated into two parts by a distinct transverse vein, the posterior part nearly rectangular, shorter than anterior part. Cell d2 narrower than d1. Anal-most and middle chords narrow and nearly parallel; basal-most chord extending from basal half of middle chord. Apical field short and rounded, with 3 wide cell alignments posterior to mirror and a narrow apical alignment; veins cream-coloured. Lateral field with 5 projections of Sc. Epiproct black. Subgenital plate pale cream-coloured with median area and anterior and posterior margins black.

GENITALIA. Very similar to *N. vittatus* (Fig. 16E) but differ by pseudoeipiphallus faintly less robust and broad, anterior margin more strongly concave. Rami more strongly curved.

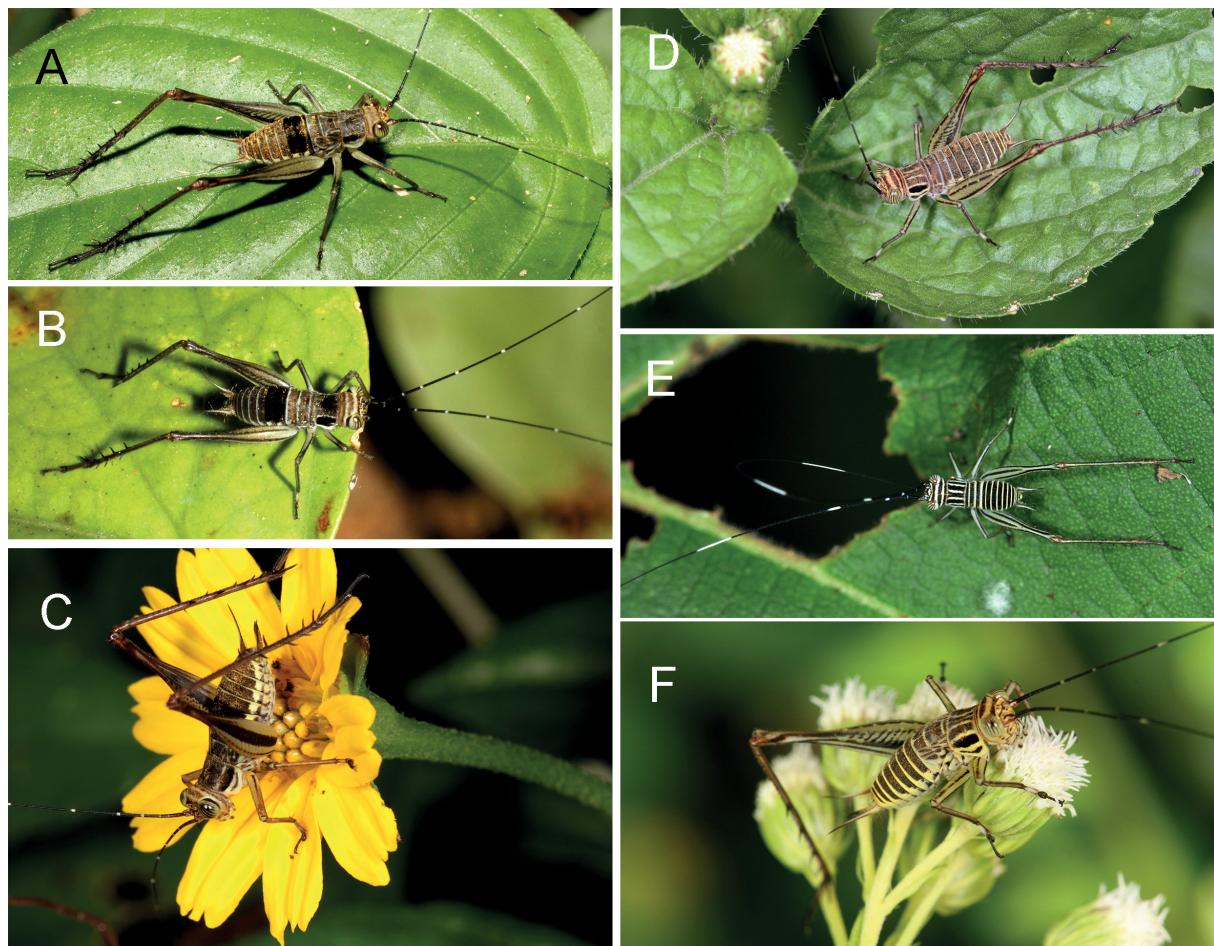

Fig. 24. Nymphs in their natural environment. **A–C.** *Nisitrus malaya* Robillard & Tan sp. nov. **D–F.** *N. vittatus* (Haan, 1844). Photograph credit: Ming Kai Tan.

Females (n = 5)	13 (13)	1–3	17 (17)	2–5	2–3	11.1–13.7 (12.3)		

Female

FOREWINGS. FW colouration (Fig. 14F): cells black, veins generally cream-coloured. Without distinct longitudinal white stripe around region of CuA, M and R with distinct margin from black colouration on dorsal field; Sc projections cream-coloured basally, black apically. Lateral field dark. FW venation: 6–7 strong longitudinal veins on dorsal field; lateral field with 6 projections of Sc.

GENITALIA. Ovipositor about as long as FIII. Copulatory papilla conical, small and stout; apex folded ventrally, short, pointed; dorsal face with a sclerotized area; ventro-anterior end forming a truncated lobule (Fig. 17J–K).

Juvenile (Fig. 24 A–C)

Differing from that of *N. vittatus* by darker colouration, usually grey, never as white as *N. vittatus*. Stripes on head similar to *N. vittatus* but sometimes very faint; pronotum dorsal disk homogeneously dark grey, without longitudinal stripes; sometimes with a large velvety black spot. Legs grey with dark stripes, but stripes not as distinct as in *N. vittatus*. Abdominal tergites dark grey, their posterior margins thinly lined with yellow, not forming a pattern of transverse stripes. In some individuals, first and second abdominal tergites with a particularly dark (black), velvety band.

Measurements

See Table 8.

Ecology

This species can be found among shrubs and herbaceous plants (but not grasses) (Fig. 27). The adults and nymphs from Singapore and Malaysia (previously reported as *N. vittatus*) have been reported to feed on the flower parts of a varieties of native (e.g., *Dillenia suffruticosa* (Griff.) Martelli) and exotic weedy (e.g., *Lantana camara* L.) plant species (Tan et al. 2017). They also feed on the foliages of understory plants such as *Piper sarmentosum* Roxb. (Fig. 27). In Singapore, *N. malaya* sp. nov. can be found abundantly in the understory where *Piper sarmentosum* dominates.

Distribution

Malay Peninsula (Singapore and Peninsular Malaysia [northern limit at the state of Penang]) (Fig. 5).

Type locality

Singapore.

Calling song (Singapore, n = 4 males, 20 echemes; MNHN-SO-2851–2854) (Fig. 25A–C)

At 27.3°C, the calling song consists of bouts of highly variable length, ranging from a few seconds to several minutes. Each bout is composed of short echemes made of triplets of syllables; echeme duration is 32.3 ± 2.8 ms (29.0–37.56 ms); echeme period is 64.5 ± 4.3 ms (59.5–75.5 ms); downtime between consecutive echemes is 32.1 ± 4.4 ms (24.3–41.3 ms). Durations for the first to third syllables of the triplet

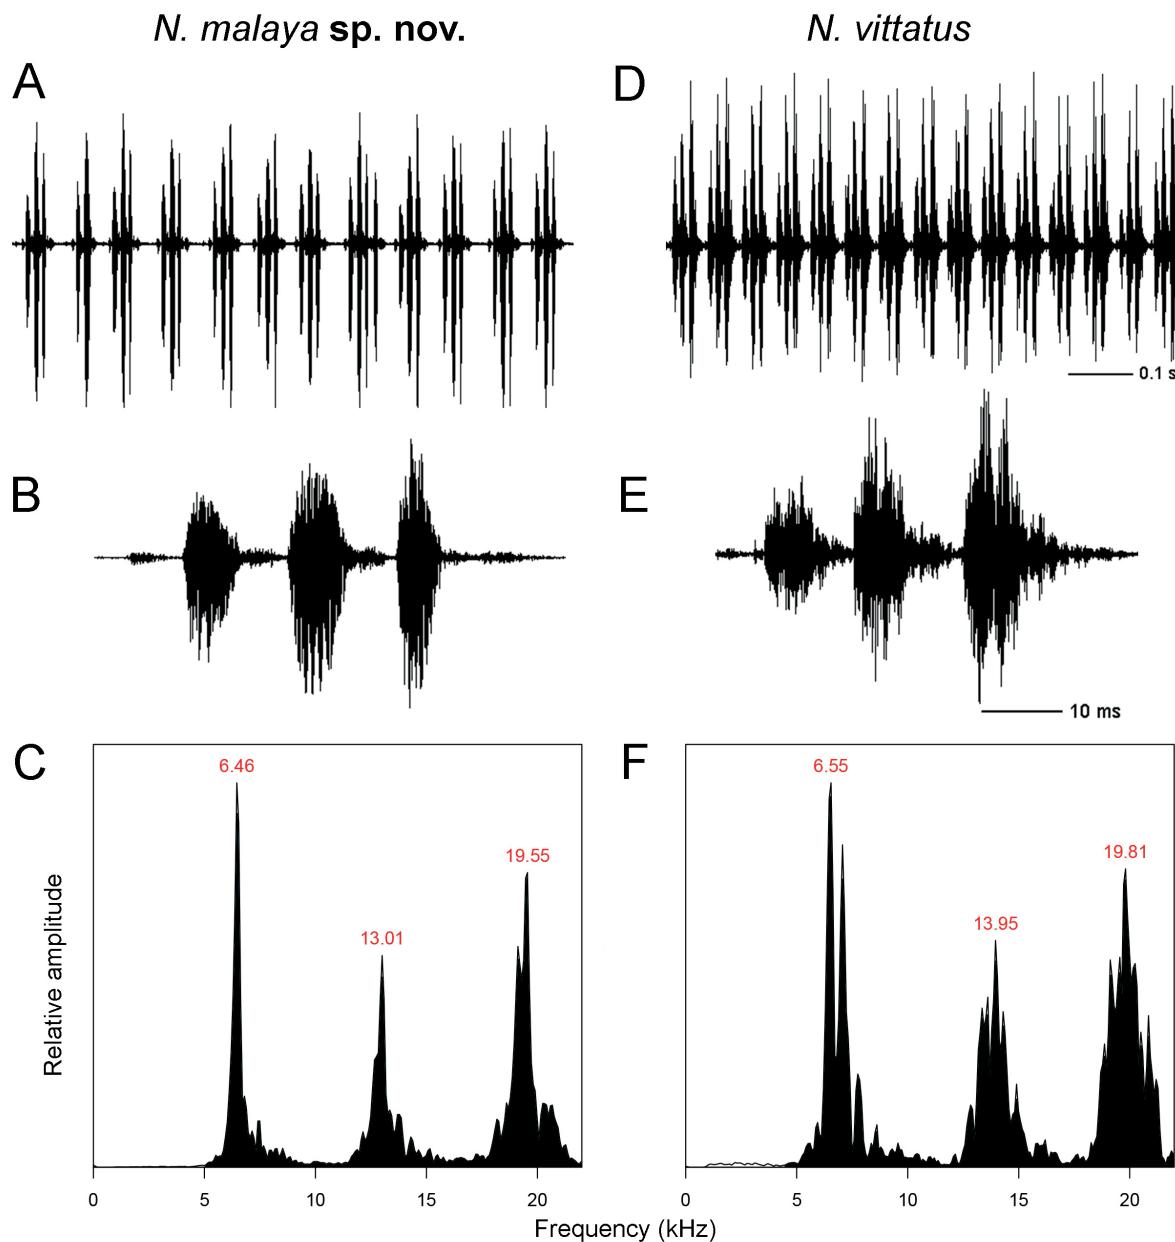

Fig. 25. Acoustics of *Nisitrus malaya* Robillard & Tan sp. nov. (A–C) and *N. vittatus* (Haan, 1844) (D–F). A, D. Series of echemes. B, F. One echeme. C, F. Spectral plot of one echeme.

are as follows: 6.1 ± 1.5 ms (3.7–8.0 ms), 6.7 ± 2.7 ms (2.5–10.6 ms) and 5.8 ± 2.9 ms (3.0–11.2 ms). Call spectrum consists of a series of harmonics with three distinct peaks in the first three harmonics: first harmonic (fundamental frequency) at 7.35 ± 1.28 kHz (6.201–9.39 kHz), which is also the dominant frequency; second harmonic at 13.33 ± 1.01 kHz (12.23–15.07 kHz); third harmonic at 18.88 ± 0.77 kHz (17.23–20.07 kHz).

Remarks

We split the species previously recognised as *N. vittatus* into two distinct species after integrating evidence from general and nymphal colouration, female genitalia morphology, acoustics, DNA (12S sequence) and distribution. In terms of adult morphology, the new species is very similar to *N. vittatus* in habitus, other than being darker in colouration. The male genitalia are not always distinguishable between these

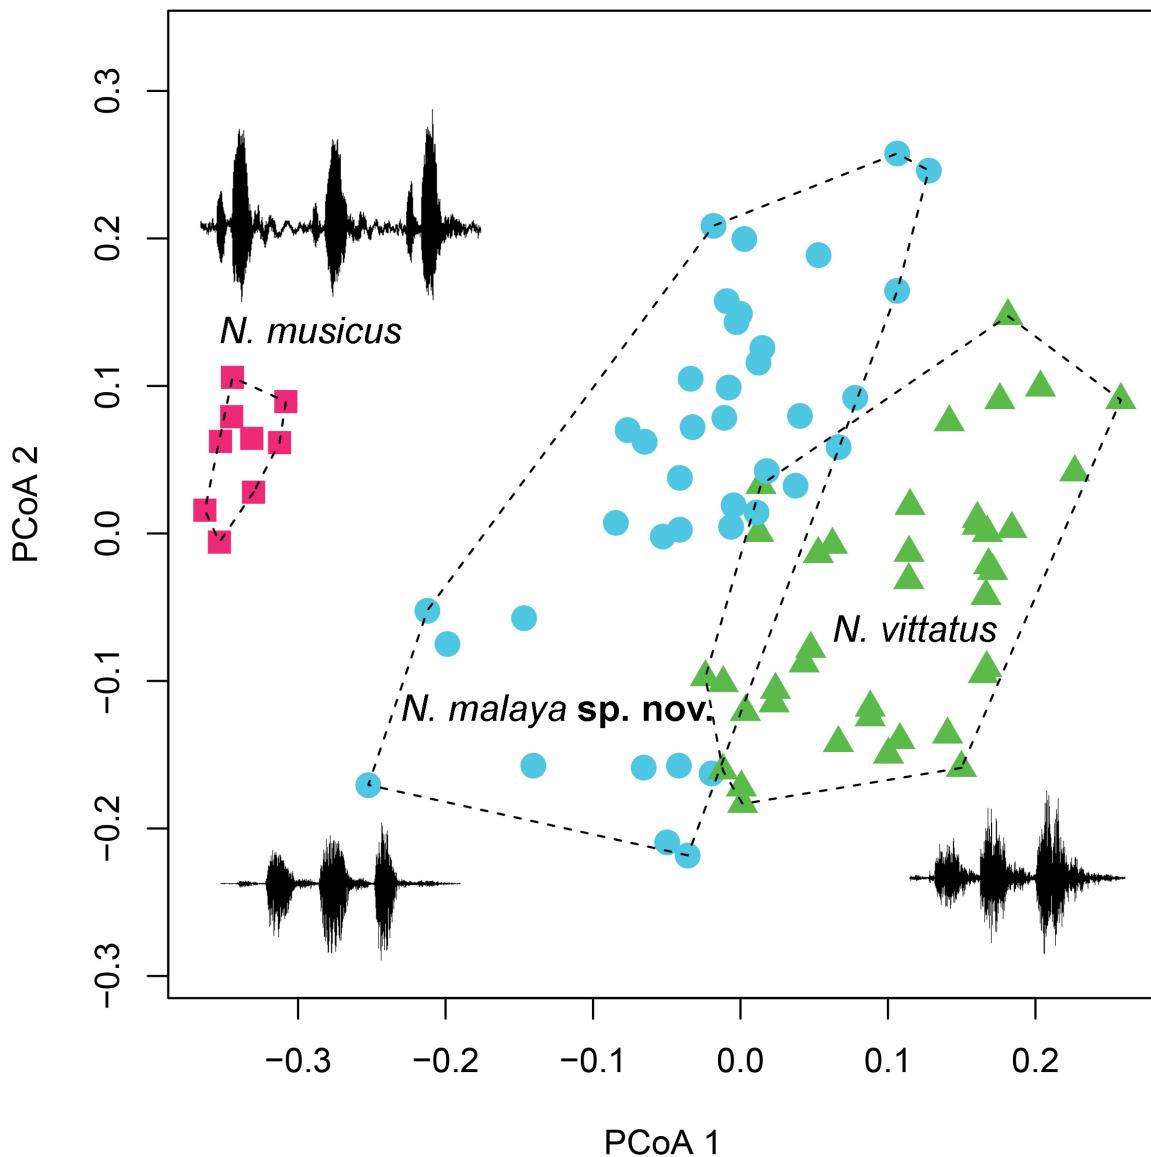

Fig. 26. Principal Coordinates Analysis (PCoA) of the acoustic properties of the calling songs of *N. vittatus* (Haan, 1844), *N. malaya* Robillard & Tan sp. nov. and *N. musicus* Ingrisch, 1987.

Fig. 27. A. Habitat where *Nisitrus vittatus* (Haan, 1844) can be found in Sungai Belalong in Brunei. B. Habitat where *Nisitrus malaya* Robillard & Tan sp. nov. can be found in Singapore. The arrows point at the type of plants (*Macaranga* sp. in A, *Piper sarmentosum* Roxb. in B) on which *Nisitrus* can be found in relatively large numbers. Photograph credits: Yale-NUS students (A), Ming Kai Tan (B).

species; but the sclerotization of the female genitalia can be differentiated. However, the colour patterns in the nymphs are drastically different. Likewise, a multivariate analysis of the call properties also showed distinct calling songs. The 12S gene tree also demonstrates that the two species form distinct clades. Lastly, the new species occurs in Malay Peninsula whereas *N. vittatus* occurs in Borneo and Sumatra. Integrating these pieces of evidence indicates that *N. vittatus* and *N. malaya* sp. nov. are indeed separate species having probably diverged recently, despite the similarities in adult habitus and male genitalia.

***Nisitrus maculosus* (Walker, 1871) nomen dubium, new status**

Table 2

Nisitra maculosa Walker 1871: 14.

Nisitra maculosa – Kirby 1906: 87.

Nisitrus maculosus – Chopard 1968: 353. — Cigliano *et al.* 2020 (Orthoptera Species File online).

Type locality

Indonesia: Maluka, Seram Island.

Type details

Male, not located.

Remarks

According to the uninformative original description, the type of the species is from Seram Island, while no species of *Nisitrus* has ever been recorded in the region of Maluku Archipelago (Indonesia). In addition, the description mentions that the eyes are little prominent, and that the FWs extend beyond the abdomen, which is not compatible with any other species of *Nisitrus*. With the type missing, we consider this species as nomen dubium (new status).

***Nisitrus marginatus* Walker, 1869 junior synonym of *Nisitrus vittatus* (Haan, 1944), syn. reinstated**

Table 2

Nisitra marginata Walker, 1869: 92.

Nisitrus vittatus – Saussure 1878: 653. — Chopard 1968: 352.

Nisitra vittata – Kirby 1906: 87 (junior synonym).

Nisitrus marginatus – Otte 1994: 67 (name reinstated). — Cigliano *et al.* 2020 (Orthoptera species File Online).

Material examined

Syntype

INDONESIA – Sumatra • 1 ♀; Stamford Raffles leg.; NHMUK 012497570.

Remarks

It is unclear why Otte (1994) reinstated *N. marginatus* as a valid species, even though earlier literature had already synonymised this species under *N. vittatus*. Based on the observation of a female syntype showing no difference with *N. vittatus*, we synonymise *N. marginatus* again under *N. vittatus*.

Figs 5, 7F, 9B, 10G, 11G, 12G, 13F, 14G, 16F, 17L–M, 26, 28; Tables 1–2, 9

Nisitrus musicus Ingrisch, 1987: 178.

Nisitrus musicus – Tan *et al.* 2019: 303. — Cigliano *et al.* 2020 (Orthoptera Species File Online).

Diagnosis (revised from Ingrisch, 1987)

Frons whitish with a black stripe between eyes and black mouthparts; femora reddish brown with a black stripe dorsally; male genitalia with pseudopiphallus slenderer than in congeners. This species is most similar to *N. danum* sp. nov., also from Borneo, from which it differs by mouthparts black (instead of yellow), FIIIs black dorsally and female papilla. While this species is restricted to the highlands in the Kinabalu range, *N. danum* sp. nov. occurs in the Danum Valley and Tawau Hill areas at the east of Sabah. It is also similar to *N. vittatus*, *N. crucius* sp. nov. and *N. malaya* sp. nov., from which it differs by slightly larger and slenderer habitus, frons whitish with black front head and mouthparts, FIIIs with a black pattern dorsally, and slenderer pseudopiphallus.

Additional description (after Ingrisch 1987)

Male

GENITALIA (Fig. 16F). Pseudepiphallus very slender and elongated, distinctly longer than wide, anterior and anterior margins gently concave. Pseudepiphalllic lophi slightly longer than wide (at base), subacute and slightly folded dorsally at apex, sclerotized laterally only, widely spaced apart from each other. Rami straight, swollen preapically, slightly diverging. Pseudepiphalllic parameres narrow, diverging posteriorly, their basal sclerite short and narrow. Ectophallic lateral sclerites appearing rounded. Ectophallic apodemes straight and parallel. Endophallic sclerite elongated, its posterior lateral arms short.

Female

GENITALIA. Copulatory papilla conical, smaller and stout; apex folded ventrally, elongated, pointed; dorsal face with a weakly sclerotized area; at ventro-anterior end a narrow oblong rim (Fig. 17L–M).

Juvenile (Fig. 28D–E)

Similar to adults in colour patterns, but younger instars differ by pronotal disk grey with dark longitudinal stripes, lateral lobes with a grey longitudinal stripe slightly ventral of the dorsal-third, sometimes in femora with white dorsal stripe, FIII with a white dorsal stripe at basal half. Legs darker in older instars, similar to adults.

Measurements

See Table 9.

Ecology

Adult and nymphal individuals have been observed to aggregate in large number (~20 individuals) on the same plant (Fig. 28E).

Distribution

Borneo (Mount Kinabalu, Trus Madi, Tenompok, Tenom Keningau in Sabah) (Fig. 5).

Type locality

Borneo: Sabah: Mount Kinabalu.

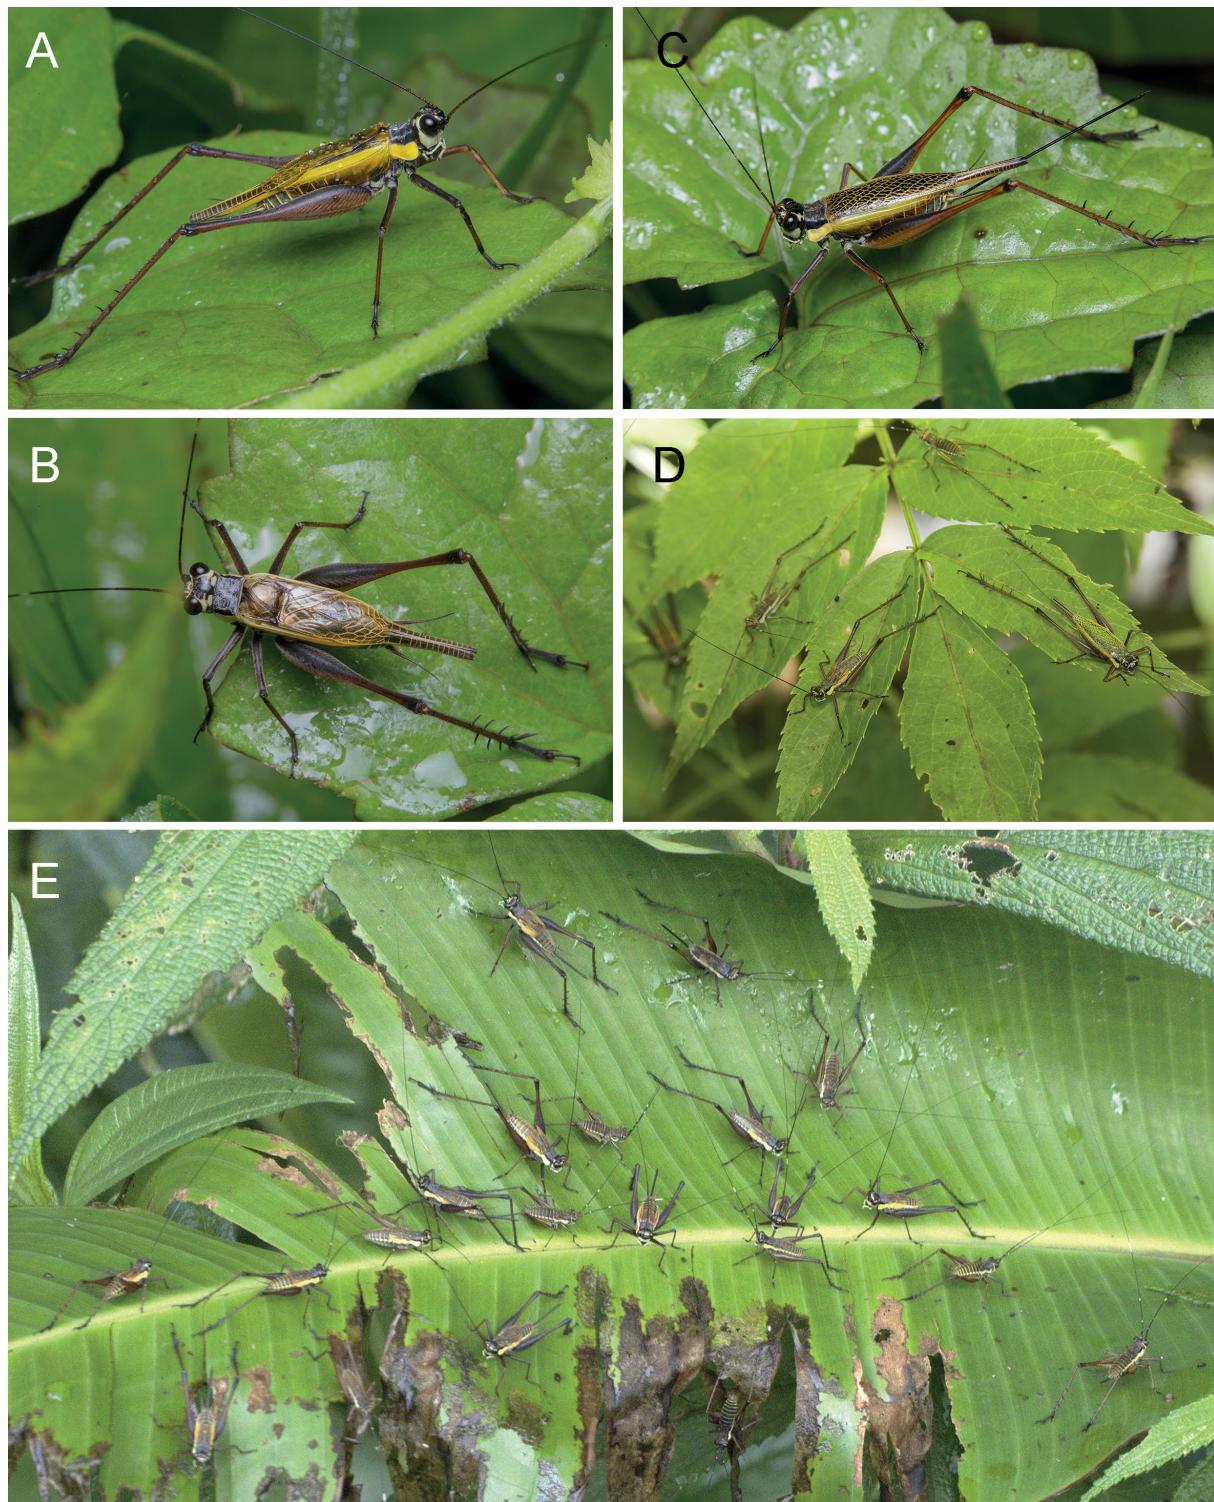

Fig. 28. *Nisitrus musicus* Ingrisch, 1987 in its natural environment. **A–B.** Adult ♂♂. **C.** Adult ♀. **D–E.** Aggregations of adults and nymphs. Photograph source and credits: iNaturalist; Marcus Ng (A–D), Kaitlyn O'Brien (E).

Females (n = 5)	12–13 (13)	2–4	20–23 (21)	2–6	2–3	16.3–22.5 (19.3)		

Calling song (n = 1 male, 9 echemes, MNHN-SO-2020-2857)

The calling song consists of long homogeneous bouts formed of very short echemes consisting of doublets of syllables; echeme duration is 29.7 ± 1.1 ms (28.4–31.3 ms); echeme period is 72.2 ± 2.1 ms (69.8–76.8 ms); downtime between consecutive echemes is 42.5 ± 2.2 ms (39.4–45.9 ms). Duration for first and second syllables of the doublets are as follows: 7.5 ± 0.6 ms (6.6–8.1 ms) and 18.7 ± 1.5 ms (15.8–20.5 ms); with second syllable usually with greater amplitude than the first. The song spectrum consists of a series of harmonics, with two main peaks in the first two harmonics: first harmonic (fundamental frequency) which is also the dominant frequency peaks at 5.46 ± 0.03 (5.42–5.51) kHz; second harmonic peaking at 10.93 ± 0.04 (10.88–11.02) kHz.

Nisitrus rindu Robillard & Tan sp. nov.

urn:lsid:zoobank.org:act:A3AE87F7-8196-4C9B-BDEF-8E9D21B92BE5

Figs 5, 9C–D, 10H, 11H, 12H, 14H, 17N–O; Tables 2, 10

Nisitrus brunnerianus – Robillard & Desutter-Grandcolas 2004a: 276 (morphological phylogeny).

Diagnosis

This species differs from all known congeners by the combination of these characters: dorsum of head cream-coloured with a black band or T-shaped marking; frons completely black; pronotal lateral lobes yellow, their anterior ventral corner black. Female FW dorsal field with cells almost completely black; veins yellow; longitudinal veins on dorsal field with many more cross-veins, creating a net-like mosaic; lateral field with M, R cream-coloured. This species is similar to *N. insignis* by pattern on head dorsum, but differs by frons completely black (instead of yellow), unique pronotum colouration and female FW lateral field with M and R cream-coloured (instead of dark coloured). This species is also similar to *N. brunnerianus*, which probably occurs in sympatry, and *N. hughtani* sp. nov. by dark frons, but differs by the characteristic pattern on dorsum of head and pronotal lateral lobe, and by female FW lateral field hyaline in ventral half. It also differs from the sympatric *N. vittatus* and *N. crucius* sp. nov. by the black frons, pronotum lateral lobe and FW colouration.

Etymology

This species name refers to the word ‘rindu’, which means ‘love’ [verb] in Iban [a group of indigenous people from Borneo] language and ‘home-sickness’ = ‘miss’ [verb] in Bahasa Melayu (Malay language)

and Indonesian. This new species is dedicated to the front-liners fighting against the COVID-19 pandemic who were far from their homes and loved ones during the early phase of the global pandemic (when the species' name was chosen).

Material examined

Holotype

MALAYSIA – Sarawak • ♀; Mount Murud; 6500 ft a.s.l.; 3°54'28.44" N, 115°29'12.68" E; 15 Apr. 1979; identified as *Nisitra brunneriana* by L. Chopard; MNHN-EO-ENSIF10939.

Paratypes

INDONESIA – Kalimantan • 3 ♀; “West Borneo, Midden” [borders of Apokajan, Boeloengan and Beraoe]; 1°58'43" N, 116°6'43" E; 15–20 Oct. 1925; H.C. Robillard 2004; MNHN-EO-ENSIF10943.

MALAYSIA – Sabah • 1 ♀; near Long Pasia “Long Pa Sia”; 4°24'22.05" N, 115°43'40.97" E; 1020 m a.s.l.; 1–14 Apr. 1987; C. v. Achterberg leg.; RMNH • 1 ♀; same collection data as for preceding; PII: N57; RMNH. – Sarawak • 1 ♀; Mount Tibang; 1°39' N, 114°34' E; 1700 m a.s.l.; E.G. Mjöberg leg.; MNHN-EO-ENSIF10944.

Description

Relatively large for the genus, colouration contrasted (Fig. 9C–D). Vertex cream-coloured with a variable longitudinal black band and one or two faint transverse black bands forming a T- or ‘+’-shaped black pattern (Fig. 11H). Scapes black, posterior end red brown. Antennae red brown with some segments black. Frons and face part of fastigium completely black, without yellow spots or bands (Fig. 10H). Mouthparts dark red brown to black. Maxillary palpi cream-coloured (Fig. 10H). Head lateral side black, sometimes with a small yellow spot at the ventro-posterior margin of eye (Fig. 12H). Pronotal disk generally black with lateral and posterior margins yellow (Fig. 11H); pronotal lateral lobe yellow, its ventro-anterior corner black (Fig. 12H). Legs red brown. FIIIs dark red brown, their inner basal area black; knees dark brown to black; TIIIs brown with black spines and spurs, dark brown to black near distal end; tarsomeres dark brown to black. Hindwings hyaline brown, with a longitudinal transparent window near external-basal area; longer than FWs, forming a dark brown tail exceeding FWs more than twice as long as pronotum. Abdomen generally black.

Male

Unknown.

Female

FOREWINGS. FW dorsal field with cells almost completely black; veins almost always yellow (Fig. 14H). Lateral field with M and R cream-coloured, sometimes with a cream-coloured patch at base; otherwise transparent or dark. FW venation: longitudinal veins on dorsal field with many cross-veins, creating a thin net-like mosaic.

GENITALIA. Ovipositor distinctly longer than FIII; apex thin. Copulatory papilla conical, smaller and stout; apex folded ventrally, elongated, pointed; dorsal face with a sclerotized area; ventro-anterior end an oblong rim (Fig. 17N–O).

Measurements

Nisitrus sumatrensis (Rehn, 1909) junior synonym of *N. insignis* Saussure, 1878, syn. nov.

Table 2

Crystallomorpha sumatrensis Rehn, 1909: 209.

N. vittatus – Chopard 1968 12: 352.

Nisitrus sumatrensis – Otte 1994: 67. — Cigliano et al. 2020 (Orthoptera Species File online).

Material examined**Holotype**

INDONESIA – Sumatra • ♂; R. Weber leg.; AMNH.

Type locality

Indonesia: Sumatra.

Remarks

Based on the study of the type from Sumatra, we consider *N. sumatrensis* as a junior synonym of *N. insignis*, even though the colour pattern of the types of both species is slightly different. After the examination of the material from Sumatra identified “*N. sumatrensis*” and “*N. insignis*”, we observed that the colour patterns form a continuum between a lighter version in *N. insignis* and the darker, more contrasting specimens previously identified as in the type of *N. sumatrensis*. There are also little diagnostic differences in the male and female genitalia for both series.

Nisitrus marginatus – Otte 1994: 67.

Nisitrus cf. vittatus – Vicente *et al.* 2017: 2203 (molecular phylogeny).

Revised diagnosis

Species of average size, colouration contrasting with black and yellow, characterised by black vertex, frons yellow, orange brown legs. Male area between M and R yellow, veins black or yellow; cells beneath R partly yellow, otherwise transparent. Anal-most and middle chords distinctly diverging apically, basal-most chord extend from midpoint/after midpoint of middle chord. Female copulatory papilla without truncated lobule at ventro-anterior end. Species very similar to *N. malaya* sp. nov., from which it differs by male genitalia with pseudopiphallus faintly less robust, narrower, anterior margin less concave; female copulatory papilla without truncated lobule at ventro-anterior end. Juvenile differs strikingly in colour patterns. Male calling song also differs by shorter echeme period.

Material examined

Neotype

INDONESIA – **Sumatra** • ♂; Wai Lima, “Z. Sum.” [South Sumatra], Lampungs; 5°25'38.06" S, 105°01'22.37" E; Nov.–Dec. 1921; Karny and Siebers leg.; RMNH.

Redescription

Size average (Figs 2, 23E–H), similar to *N. malaya* sp. nov. but differs by slightly lighter colouration, male genitalia, female copulatory papilla and juvenile colouration.

Male

GENITALIA (Fig. 16G). Pseudepiphalus relatively slender, slightly longer than broad, anterior margin straight, posterior margin indented in median area to faintly concave, lateral margins with basal half converge posteriorly, apical half somewhat parallel. Pseudepiphallic lophi slightly longer than wide (at base), sclerotized laterally only and covered with strong short setae; their apex slightly folded dorsally and sub-obtuse; moderately spaced apart from each other. Similar to *N. malaya* sp. nov. but differs by pseudepiphalus faintly more robust and broad, anterior margin more straight. Rami more straight.

Female

GENITALIA. Copulatory papilla conical, smaller and stout; apex folded ventrally, elongated, pointed; dorsal face with a sclerotized area; ventro-anterior end with an oblong rim, without truncated lobule (Fig. 17P–Q).

Juvenile (Fig. 24D–F)

Characterised by pale white or yellow colouration with numerous dark stripes all around body. Dorsum of head with three transverse black stripes that extends to gena. Eyes with numerous dark stripes. Fastigium with margin black; antennal black with pale rings; frons with a few black spots; palpal segments white with apices black. Pronotum with three thick, dark longitudinal stripes on dorsal disk, one very thick velvety black stripe between dorsal disk and lateral lobe; another curved stripe on lateral lobe ventral of the thick stripe; these stripes not reaching margins. Fore and middle legs with longitudinal dark stripes, two on each face, usually one dorsal and one ventral. FIII with longitudinal dark stripes, two dorsally, and two ventrally. Thoracic (excluding pronotum) and abdominal tergites typically dark or greyish, anterior margin dark, their posterior margin whitish forming a homogeneous light/dark striped pattern. Cerci whitish with a black stripe.

Measurements

See Table 11.

Ecology

This species can be found among shrubs and herbaceous plants (but not grasses) at the forest edge (Fig. 27A). Similar to *N. malaya* sp. nov., the adults and nymphs of this species have been observed in Brunei Darussalam to feed on the flower parts of a varieties of native and exotic plant species (Tan *et al.* 2017).

Distribution

Sumatra, Borneo.

Type locality

Indonesia: Sumatra: Lampungs, Wai Lima.

Calling song (Kuala Belalong, n = 2 males, 20 echemes; MNHN-SO-2020-2859 to MNHN-SO-2020-2860) (Fig. 25D–F)

At 27.0°C, the calling song consists of long homogeneous bouts made of short echemes consisting of triplets of syllables; echeme duration is 32.47 ± 3.79 ms (27.00–38.65 ms); echeme period is 55.20 ± 5.90 ms (50.52–74.27 ms); downtime between consecutive echemes is 22.73 ± 7.26 ms (14.16–41.82 ms). Durations for the first to third syllables of the triplet are as follows: 6.93 ± 1.73 ms (4.57–9.95 ms), 7.51 ± 2.03 ms (4.80–11.67 ms) and 7.22 ± 2.82 ms (3.24–12.44 ms). The call spectrum consists of a series of harmonics with three distinct peaks corresponding to the first three harmonics: first harmonic (fundamental frequency) at 6.86 ± 0.28 kHz (6.46–7.15 kHz), is usually the dominant frequency; second harmonic peaking at 14.08 ± 0.39 kHz (13.35–14.64 kHz); third harmonic peaking at 19.96 ± 0.35 kHz (19.12–20.67 kHz).

Remarks

See *N. malaya* sp. nov. for arguments about considering two distinct species.

About synonymy of *Nisitrus marginatus* (Walker, 1869) under *N. vittatus*, considering that *N. vittatus* is variable in colouration and widely distributed in Borneo and Sumatra, and that the only known syntype

of *N. marginatus* from Sumatra resembles *N. vittatus*, we consider the species described by Walker (1869) as a junior synonym of *N. vittatus*.

Discussion

This extensive taxonomic revision of the genus *Nisitrus* allowed us to assess the validity of most of the existing species, to redefine the genus and to describe five new species from Malay Peninsula and Borneo. We consider *N. sumatrensis* (Rehn, 1909) as a junior synonym of *N. insignis* Saussure, 1878; and *N. marginatus* (Walker, 1869) as a junior synonym of *N. vittatus*, and *N. maculosus* (Walker, 1871) as a dubious name (Table 2). In total, we recognise 10 valid species in the genus.

We observed that unlike typical crickets and other eneopterines recently revised taxonomically (e.g., Jaiswara *et al.* 2018, 2019; Robillard *et al.* 2014), male genitalia may not always be useful for differentiating species in *Nisitrus*. Male genitalia can be variable within species of *Nisitrus*, partly due to their more membranous nature, which can be deformed due to preservation or state of specimens (e.g., age of specimen at collection date, method of preservation and/or age of specimen). Female genitalia can be more useful than male genitalia in some instances, as for example to differentiate *N. vittatus* and *N. malaya* sp. nov. In general, species were more accurately differentiated by colour patterns, especially those on the face, pronotum lateral lobes and wings. However,著色 of the head and lateral lobe of pronotum can also be variable within species (e.g., in *N. insignis* and *N. brunnerianus*), making their use as specific characters uneasy. For example, in *N. insignis*, there are two clear variants from Sumatra and the smaller neighbouring Mentawai Islands, which made us hesitate whether there were one or two distinct species. Likewise, we observed that lateral lobe of pronotum in *N. brunnerianus* can range from completely black, with a small yellow spot, to bicolour, with ventral half yellow. Surprisingly, juveniles of *Nisitrus* can be distinctly different in their live colour patterns in species which have very similar adult morphology. This is particularly the case of *N. vittatus* and *N. malaya* sp. nov. However, juveniles are unknown for most species other than from anecdotal observations. Lastly, male call properties (both time and frequency domains) can also be used as evidence for species delimitation, but recordings are also rare for most species.

Although the phylogenetic tree obtained from the 12S mitochondrial marker probably does not reflect robust evolutionary relationships of the species of *Nisitrus*, this molecular marker allowed us to test species delimitation for the well-sampled species. It strongly supported the fact that *N. malaya* sp. nov. was a distinct species from *N. vittatus*, adding to the evidence from juvenile著色 and acoustics. To reconstruct a robust phylogeny, multigene or genomic data should be used, in particular to include

species only known by old specimens. A study on the phylogeny and evolution of *Nisitrus* was previously impossible because the taxonomy of this genus still warranted a revision to describe unknown species and to identify diagnostic characters to delineate species. Nonetheless, based on this first taxonomic revision of this genus, it is now possible to follow up with a new study to investigate questions on the evolution, speciation and biogeography of these crickets.

The distribution map (Fig. 5) based on this study shows that *Nisitrus* can be found in Malay Peninsula, Sumatra, Borneo and Java. Two species are found in Malay Peninsula, three in Sumatra and six in Borneo. We also found that in many parts of the distribution of *Nisitrus*, two or more species can coexist. This is the case for *N. insignis* and *N. hughtani* sp. nov. in Sumatra as well as *N. vittatus*, *N. crucius* sp. nov. and *N. rindu* sp. nov. in parts of Borneo. However, we postulate that samplings in Borneo and Java are probably insufficient and the current map does not represent the true diversity and species distribution in these islands.

Lastly, there is still very little known about the ecology of most species as most natural history notes are anecdotal. This taxonomic study allows for future investigations on ecological questions, such as what predicts the activity, abundance and diversity of *Nisitrus*, and what the microhabitat, habitat and dietary preferences are (Fig. 28). Given that species of this genus can be locally abundant and charismatic, *Nisitrus* can potentially be used as flagship and indicator species when a better understanding of their ecology and behaviour is available.

Acknowledgements

We thank Andrej Gorochov (ZIN) for providing samples from the collections of Saint Petersburg; Jérôme Constant and Carole Paleco (RBINS) for their help during the study of the collections of the Royal Belgian Institute of Natural sciences, Brussels, funded by the SYNTHESYS European program (BE-TAF-6640); Rob de Vries, Caroline Pepermans and Luc Willemse (NBB Naturalis) for their help with the Leiden collections; Sigfrid Ingrisch (ZFMK) for providing specimens from Sumatra and Borneo; Ellen Sandström Biological Museum, Lund University; Martin Husemann for the loan of material from Hamburg museum; Russell Cox and Dan Bickel for the loan of material from the Australian Museum; Judith Marshall and George Beccaloni (BMNH) for their help during the study of the Natural History Museum of London collections (funded by the SYNTHESYS European program GB-TAF-531); Peter Schwendiger and John Hollier (MHNG) for their help during the study of Genève collections; and Oscar Effendi and Erni Ernawati (MZB, Indonesia) for their help during the study of eneopterine crickets in Cibinong, Indonesia (MZB), and all the other persons helping us in the collection of crickets and in some other aspects. MKT thanks Huiqing Yeo (in Brunei Darussalam), Siew Tin Toh (in Sandakan), Momin Binti, John Lee Yukang and Saudi Bintang (in Sandakan) for field assistance. The permissions for collecting and exporting material were granted by the Forestry Department, Ministry of Primary Resources and Tourism, Brunei Darussalam and the Biodiversity Research and Innovation Centre (BioRIC) (JPH/PDK/01 Pt 2 and BioRIC/HOB/TAD/51-80 respectively); and the Sabah Biodiversity Centre (JKM/MBS.1000-2/3 JLD.3 (99)) (for Sandakan). The work of MKT was supported by the Orthoptera Species File Grant 2019 under the taxonomic research project titled “Contribution to the species diversity and acoustic data on Orthoptera from Sandakan (Borneo, East Malaysia, Sabah)”; and Percy Sladen Memorial Fund (The Linnean Society of London) under the project titled “Advancing biodiversity informatics of Orthoptera from Brunei Darussalam” and the Fyssen Foundation Postdoctoral Fellowship. The authors thank Arthur Anker, Ganjar Cahyadi, Charlie Elder, Oscar Johnson, Michael Kesl, Marcus Ng, Dries Nys and Marion Vancauwenbergh, Kaitlyn O’Brien, Marcel Silvius, and James Steamer for allowing the use of their in-situ photographs; and Jeff Zhang for the recordings of *Nisitrus musicus*.
