

Idionyx montana scheint sich von *I. yolanda* Selys durch die an der Basis ungefärbten Flügel, breitere Hinterflügel und 7 Postnodalqueradern statt 5 im Vorderflügel, von *I. optata* Selys durch an der Basis ungefärbte Hinterflügel und das längere Pterostigma zu unterscheiden; von *Epophthalmia* (? *Oxygastra*) *gracilis* Burm. weicht sie durch die schwarze Costa und (nach Selys) die ungestielten Sectoren des Arculus u. a. erheblich ab. Wie das mir vorliegende ♂ zeigt, ist das achte Abdominalsegment bei diesem Geschlechte im Gegensatze zu den *Phyllomacromia* ♂♂ seitlich nicht blattartig erweitert, ein Merkmal, durch welches ein fernerer generischer Unterschied von *Phyllomacromia* Selys gegeben ist.
