Abstract

This study summarizes new and historical records of one of the least known anuran species from the Chilean Altiplano, *Pleurodema marmoratum* (Duméril & Bibron, 1840). The discovery of a new population in the Altiplano of the Región de Antofagasta extends the known distribution of this species in Chile approximately 100 km south.

Key Words

Andes, Anura, highlands, Leptodactylidae

Pleurodema marmoratum (Duméril & Bibron, 1840) is a native anuran of the South American highlands, which is distributed across Peru, Bolivia, Argentina and Chile in an altitudinal range from 3,000 to 5,200 meters above sea level (Duellman and Veloso 1977; Seimon et al. 2007). Although this species is widely distributed in the center of the Altiplano basin, there are few reports of populations located at the margin of its distribution (e.g., in Chile and Argentina). In Chile, the known geographical distribution of *P. marmoratum* is disjunctive due to the fragmented nature of the habitat it occupies (i.e., high Andean or Altiplano wetlands) and to the fact that its populations are separated by long distance. This species was first recorded in Chile by Ceï (1958), who identified two specimens collected in the town of Caquena, located in northern Chile (Región de Arica y Parinacota). Subsequently, this species was reported in the surround-

ing area of Putre and Parinacota in the Lauca National Park (Veloso et al. 1982), not far from the record by Ceï (1958). Most recently, the distribution of *P. marmoratum* extended 145 km south, up to the Quebe wetland (Región de Tarapacá), including the southern area of the Lauca National Park as well (Sallaberry et al. 2007). Except for two poorly documented records further south (Bonacic et al. 2015), no new reports were published on the presence of this species in Chile. In fact, *P. marmoratum* has been categorized as “Endangered” and “Rare” inside Chilean territory (Comisión Nacional del Medio Ambiente 2007), since its populations occupy a small geographic area and are restricted to a very specific habitat. Nevertheless, the designation of this conservation status could be a consequence of the scarcity of herpetological explorations in the Andean territory/region of northern Chile, just as it has been described for other groups of anurans distributed

Figure 1. Specimens of *Pleurodema marmoratum* and their respective habitats. The localities sampled are as follows: A) Colpa, B) Ocacucho, C) Piga, and D) Coska.

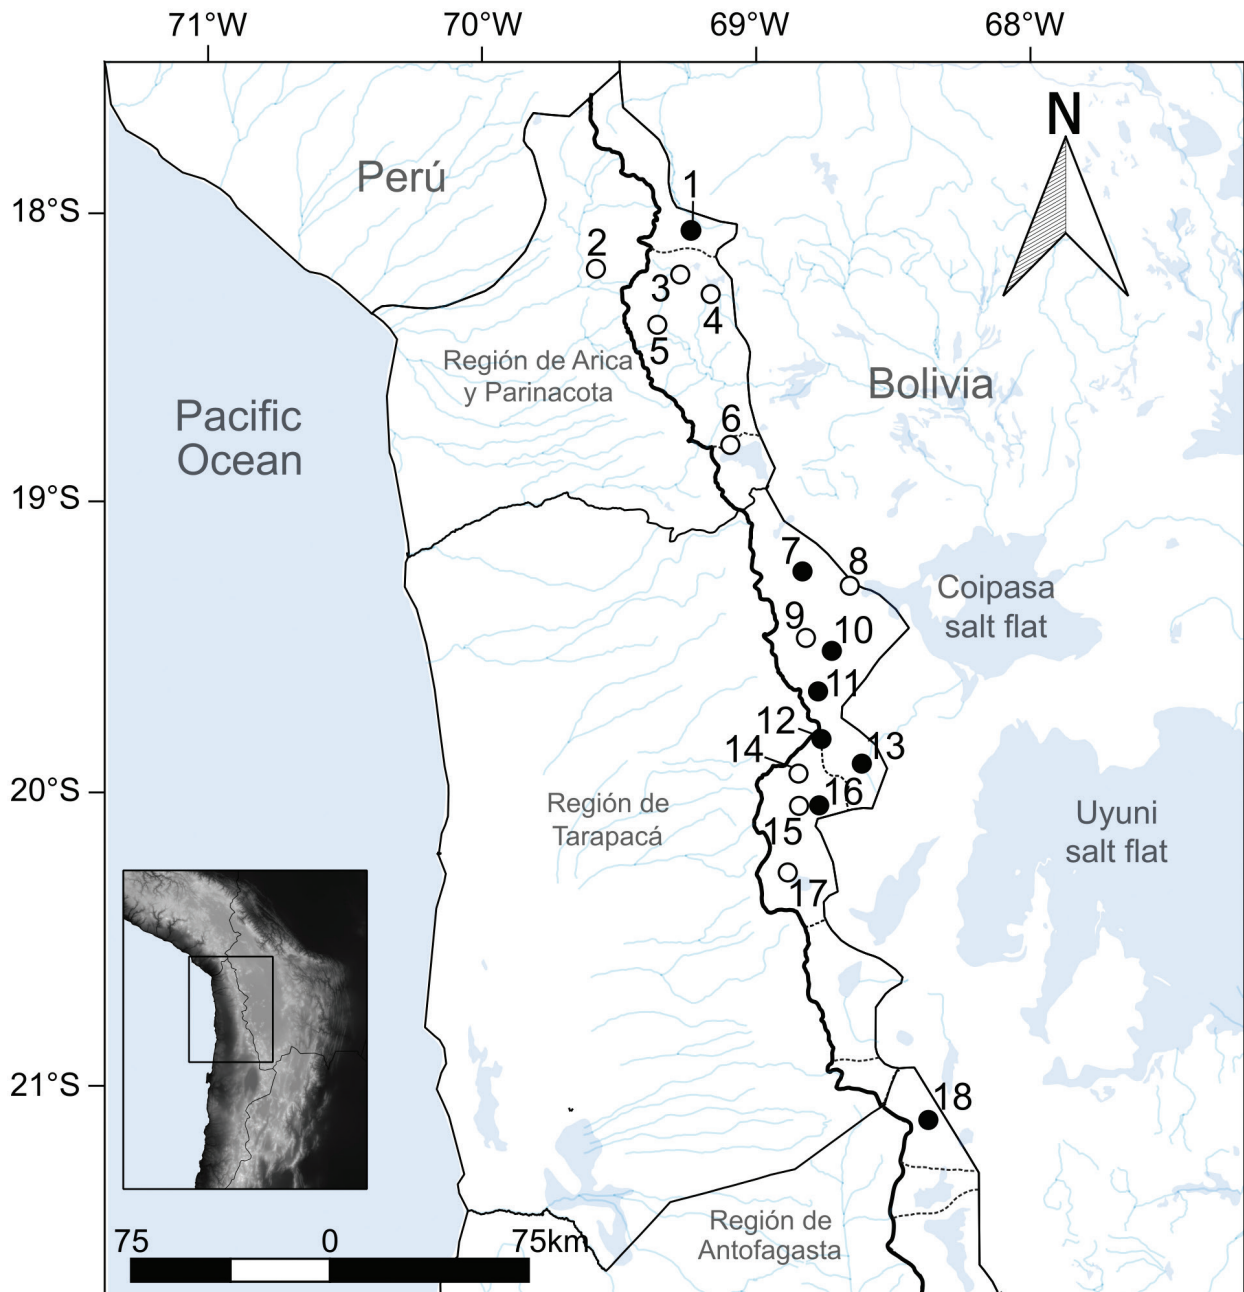

Figure 2. Geographical distribution of *Pleurodema marmoratum* populations from the Chilean Altiplano. The numbers on the circles are referred to in Table 1.

in that area, such as the case of the genus *Telmatobius* (see Sáez et al. 2014). Therefore, this work synthesizes the historical records and contributes new findings within the known distribution of *Pleurodema marmoratum* in Chilean territory, including a record that extends the distribution to the Altiplano of the Región de Antofagasta.

The findings documented in this work correspond to records made between 2014 and 2019, during field campaigns carried out in the high Andean area of the Región de Arica y Parinacota, Región de Tarapacá and Región de Antofagasta, Chile. The specimens of *P. marmora-*

tum reported here were found under rocks located at the margins of the streams and wetlands prospected in the Altiplano (Figure 1), and were identified based on the diagnosis provided by Veloso et al. (1982). The specimens found were neither collected nor sampled.

The geographical distribution of *P. marmoratum* in the Chilean Altiplano is summarized in Figure 2 and Table 1. Previous records of this species are located between the Caquena (Región de Arica y Parinacota) and Quebe (Región de Tarapacá) wetlands. Moreover, we found an old record belonging to a specimen collected in the Huasco

salt flat, Región de Tarapacá, located south of the Quebe wetland (Moreno et al. 2001); however, the coordinates of the collection site were not provided. The new records of *P. marmoratum* reported here include the locality of Colpa in the Región de Arica y Parinacota, a number of localities in the Región de Tarapacá (Enquelga, Toroni, Cotaculco, Ocacucho, Cancosa and Piga), and the town of Coska, in the Altiplano of the Región de Antofagasta, all located approximately between 3,500 and 4,600 meters of altitude. The record of Coska extends the known distribution for this species in Chile to approximately 100 km south. On the other hand, it was not possible to locate the populations of *P. marmoratum* described by Veloso et al. (1982) for the Lauca National Park (Región de Arica y Parinacota), although other anuran species that were registered in that work have been observed again in nearby areas (e.g., *Telmatobius peruvianus* in Putre; Sáez et al. 2014). In this region, specimens of *P. marmoratum* were recorded in the town of Colpa, near Parinacota, at the northern end of its distribution in Chile. Colpa is a wetland near Caquena (separated by no more than 3 km). Taking into account the geographical proximity of both localities and the fact that they are connected by a branch of the Caquena river, we suggest that our record could correspond to the population of *P. marmoratum* described by Cei (1958) for the Altiplano of the Región de Arica y Parinacota.

Given that most of the new findings were made in the Región de Tarapacá (Isluga National Park), this geographical location could correspond to the center of the distribution of *P. marmoratum* in Chile. The populations of this species in the Región de Tarapacá inhabit wetlands located west of the Coipasa and Uyuni salt flats and are separated from the populations registered in the Lauca National Park by a long distance (approximately 140 km). However, a recent record for this species in

the Surire salt flat (S. Flores and E. Gutierrez, CONAF; personal communication), suggests the presence of other populations between those of Región de Tarapacá and Lauca National Park. Furthermore, the Coska population, corresponding to the new southern limit for the distribution of *P. marmoratum* in Chile, illustrates the fragmented nature of the distribution of this species. This population is widely separated from the rest of the populations present in Chile and is apparently not associated with a permanent wetland (i.e., wetland fed by melting ice). In any case, it is not surprising that the distribution of *P. marmoratum* would extend to the Región de Antofagasta in Chile, since records in Argentine territory extend to the Provincia de Jujuy (Ferraro et al. 2009).

The detection of only a few specimens in each of the prospected localities suggests that the population densities of this species are low, as previously described by the IUCN Amphibian Specialist Group (2014). The two records made in the Colpa wetland are separated by approximately 2.5 km, suggesting that *P. marmoratum* populations may cover wide areas. On the other hand, the evidence presented here could generate a change in the status of this species for Chile, since it has a wide geographical range with presence in several locations within this country, although its populations are highly fragmented.

Finally, due to the wide geographical distribution of this species and its high degree of fragmentation, it is feasible to infer that there is more than one lineage of *P. marmoratum* in Chile. Previously, Vellard (1960) recognized different subspecies of *P. marmoratum*, but Duellman and Veloso (1977) suggested that these subspecies would not be valid, pointing out that *P. marmoratum* populations are highly polymorphic, which is a hypothesis that must be reevaluated by integrative studies that cover the entire distribution of the species.
