Afrotropical species of the ancient genus *Meria* Illiger 1807
(Hymenoptera, Tiphiidae)

M. BONI BARTALUCCI

**Key words:** *Meria*, new species, Afrotropical Region.

**Introduction**

The genus *Meria* is widely spread over warmer arid and semi-arid countries of the Old World. About Afrotropical Region most of the taxa hitherto known come from Austral Africa and this study support the present state of the art, which only secondarily appears determined by the fact that South Africa has been by far the most investigated area. The most striking feature about distribution areas of the taxa here dealt with is the complete segregation between areas north of wet equatorial belt and areas south of it; none of the Austral taxa lodges in the former and vice versa for the fewer northern taxa; the sole opposing record of *M. cingulata* from Erythraea (BONI BARTALUCCI 2004) appears highly dubitative and needs confirmation. Taxa from areas North of Equator along the Sahel belt till Erythraea and Somalia are obviously considered belonging to Afrotropical fauna, even though Afrotropical taxa cohabit there with taxa of the Palaeartic genus *Poecilotiphia* Cameron 1902 and with *Meria diplochora* BONI BARTALUCCI 2008, present on the Southern Arabian Peninsula too, the latter considered pertaining to Palaeartic Region, even though it could effectively be included also into the Afrotropical fauna. Moreover the relative paucity of taxa from this area appears a bit anomalous and probably owing to a deficit of investigations. The more consistent hypothesis inferred from actually available data is that Austral Africa could be the dispersal centre of the genus,
for the Afrotropical Region at least. Here the presence of largest number of species and the broadest degree of variability occur and indicate that the group has existed for longer time than in other areas. This hypothesis could be strengthened by the unique presence in this area of the other subtribe, Braunsomerina. Compared with palaeartic members of the genus the Afrotropical taxa show an higher degree of variability about some of the main distinctive character states for the genus: namely the relative length of the mouth-parts in both sexes, which concerns more than one taxon and forces to partially modify the items 5a and 5b about the generic key of the subtribe Meriina (BONI BARTALUCCI 2007), the presence of an additional lamellar keel on the hind coxa, the particular aedeagus in some males. The lamellar extension of the keel along the fore border of the N₁ disk, present at least partially in all the palaeartic taxa, is lacking instead in the vast majority of the males of the afrotropical taxa; it is well developed only in *M. sublevis*, *M. limata*, *M. bonaespei* and poorly present in *M. servillei*, *M. erythraea*, *M. leucospila*. Unfortunately most of taxa are known only by one sex since their association actually can not be accomplished because of wanting data. Some of the few known couplings have been performed by JACOT-GUILLARMOD in paper (1961) and in labels too. Further field investigations and deeper searching into areas hitherto poorly known (Angola, Zimbabwe, Sahel) will produce probably both new sex associations and discovery of many new species.

**Material and methods**

The terminology used in the descriptions follows BONI BARTALUCCI (2004).

**Abbreviations.** Those referred to the wing structures are in italics (veins excluded).

- **A** = height (Altitudo)
- **a** = anterior
- **Ca** = head (Caput)
- **CB** = basal cell (Cella Basalis)
- **CC** = costal cell (Cella Costalis)
- **CD** = discoidal cell (Cella Discoidalis)
- **cHy** = hypostomal keel (carina Hypostomae)
- **CM** = marginal cell (Cella Marginalis)
- **cOc** = carina Occipitis (-alis).
- **CPM** = submarginal cell (Cella Para Marginalis)
- **CSM** = sub marginal cell (Cella Sub Marginalis)
- **Em** = Epimeron
- **Es** = Episternum
- **F** = female (Foemina).
- **FoO** = oral cavity (Fossa Oris)
- **G** = Gena
- **Hy** = Hypostoma
- **I** = distance (Intervallum)
- **L** = length (Longitudo)
- **l** = lateralis (lateral)
- **LA** = width (LAtitudo)
- **LaSt** = mesosternal lobes (Lamellae mesoSterni)
- **m** = median (medianus)
- **mR** = microreticulation (micro Reticulum)
- **M** = Male (Mas)
- **N₁** = proNotum.
- **N₃** = metaNotum.
- **O** = eye (Oculus)
- **p** = puncture (-s), punctured
- **P** = Propodeum
- **Pal** = labial palpus (Palpus labialis)
- **Pam** = maxillary palpus (Palpus maxillaris)
- **PoG** = genal bridge (Pons Genarum).
- **Sc₁** = Scutum.
- **Sc₂** = Scutellum.
- **Secu** = Sensilla curvata
- **Ssa** = Subantennal sclerite (Scleritis sub antenna)
- **St₃** = metaSternum
- **sul** = lateral furrow (sulcus lateralis)
- **Tsa** = supra antennal lobes (Tuberculi supra antenna)
- **X** = coXa
1819

! = Types examined; ( ) = digits between round brackets in the chorological items mean number of specimens; / / = delimit the single label. Within the descriptions of labels, italic characters mean handwriting.

The frontal aspect of the head is performed perpendicularly to the virtual plane A indicated by the relative line on the Fig. 3; dorsal and lateral aspects, perpendicular to each other, are performed along the virtual plane of the occipital carina.

The outermost pair of appendages of male genitalia will be termed "gonostylus" (with its portions basi- and disti-stylus). The drawings of the volsella and gonostylus show respectively their inner and outer aspect, unless otherwise indicated. Genitalia are settled in a solidified drop of 5,5-dimethyl hidantoin formaldehyde (5,5-DMHF) on a transparent support. Hair, punctuation and light markings have been overlooked in most of the drawings.

**Identification key**

Females .............................................................................................................................................................................................................1
Males...............................................................................................................................................................................................................24

1
a  Paramandibular process wider than aggregate length of two apical palpomeri of Pam and as long as 0.45 times maximum width of FoO
b  Genal bridge 0.6 times height of FoO in ventral aspect (Fig 4)
c  Glossa sub-triangular in ventral aspect, without any apical notch (Fig. 5)
d  The complex glossa-paraglossa strongly shorter than prementum (Fig. 5)
e  Posterior lingual plate neither elongated, neither elliptic
f  Labrum with a slightly concave ventral edge in frontal aspect (Fig. 6)

2
aa maximum length of FoO at best
bb Paramandibular process narrower than length of apical palpomerus of Pam and only 1/6 Genal bridge never more than 0.3 times height of FoO in ventral aspect
cc Glossa distinctly notched apically (well detectable in ventral aspect; less stressed in rufinodis and luteipes)
dd The complex glossa-paraglossa normally well longer than either in few cases just a bit shorter than prementum
ee Posterior lingual plate elongated and elliptic, with the main axis more than twice the minor axis
ff Labrum with a clearly convex and prominent ventral edge in frontal aspect (Fig. 40)

oinodes nov.sp.

laterally till to cover most of its surface. Median area of clypeus convex more often than not with a well expressed low and blunt vertical prominence.

b **mpm** strongly turning towards clypeus before meeting **Hyc** (Fig. 21, 39)

c Inner lobe of mandible weakly prominent, its upper sub tooth either very feeble either not expressed (Figs 38)

d Ventral **Es** completely and regularly **p** without large smooth areas just before **LaSt**. **LaSt**. More often with a cluster near their apex and a stripe of **p** along their mutual inner edge (but in **limata**)

3

aa Most of clypeus smooth and shining, with only a single row of **p**, along its ventral border and base of the lamella (Fig. 46), only in **rufinodis** and **luteipes** it resemble to state a. Median area of clypeus more often completely flat.

bb **mpm** almost straight, only scarcely turning towards to meet **Hyc.** (Fig. 47)

c Inner lobe of mandible prominent, its upper sub tooth well expressed (Figs 46). **luteipes** shows state **χ**

dd Ventral **Es** with large smooth areas near **LaSt** which is almost completely smooth, with only very few **p** at its apex at the most

10

3

a Median area of clypeus flat, without well detectable vertical prominence

b Base of hypostomal carina evenly rounded in ventral aspect (Fig. 21, 66)

c Upper sub tooth of the lobe on the inner edge of the mandible not expressed (very feeble in **inconspicua**) (Figs 18 & 20)

d Propodeal disk with a well produced median furrow and lateral punctuation

e Forewing with 2nd **SMC** present. Pterostigma with a well differentiated inner area

f Coastal vein (c) of hindwing without bristles along its edge basally to hamuli; only secondary hamuli eventually present

g Hindtibial spurs with straight subparallel edges along most of their length (tapered at their base and apex)

h 6th tergum smooth and shining without any microsculpturation (**inconspicua** shows state **γγ**)

i Metasoma without any light patches (**inconspicua** shows state **ττ**)

4

aa Median area of clypeus convex with a well expressed low and blunt vertical prominence

bb Base of hypostomal carina with a median small protuberance in ventral aspect (Fig. 29, 39)

cc Upper sub tooth of the lobe on the inner edge of the mandible feebly but clearly expressed (Figs 38)

dd Propodeal disk without any furrows or with a very short one and mostly smooth surface

e Green without 2nd **SMC**. No differentiated area within pterostigma

ff Hindwing with a series of bristles as long as, or longer than, height of the **CC** along the edge of the c basally to hamuli

gg Hindtibial spurs more or less enlarged on their apical third

hh 6th tergum with a microreticulation well detectable at ×40 magnification on the surface apically to the preapical row of pits

ii White lateral patches on 2nd and 3rd terga about all the taxa

Group of **limata** ................................................................................................................................. 6
1821

4

a  Upper sub tooth of the lobe on the inner edge of the mandible feebly expressed
b  6th tergum with a microreticulation well detectable also at less than \( \times 40 \) magnification.
c  White lateral patches on 2nd and 3rd terga

c
inconspicua (TURNER 1913)

aa Upper sub tooth of the lobe on the inner edge of the mandible not expressed
bb 6th tergum smooth and shining
cc Metasoma without any light patches

5

a  Median height of clypeus (including lamella) about 1/7 its width in frontal aspect (Fig. 18).
b  Ratio \( \text{LA} / \text{A} \) of the \( \text{N}_1 \) disk about 2 in dorsal aspect.
c  The whole of the postero ventral corner of lateral \( \text{N}_1 \) with large irregular wrinkles.
d  Propodeal disk wrinkled on its lateral fourths
e  Pterostigma with a well differentiated inner area
f  Legs and apical metameri ferruginous-brown phainoprocta nov.sp.

aa Median height of clypeus (including lamella) about 2/7 its width in frontal aspect (Fig. 20)
bb  Ratio \( \text{LA} / \text{A} \) of the \( \text{N}_1 \) disk about 2,4 in dorsal aspect.
cc Lateral \( \text{N}_1 \) without large irregular wrinkles.
 dd Propodeal disk densely \( p \) on its half anterolateral surface
e e Pterostigma without a well differentiated inner area
 ff Body and legs black, the whole of metasoma ferruginous dissimilis nov.sp.

6

a  Clypeal disk densely \( p \), and haired throughout but small lateral areas
b  \( \text{N}_1 \) and propodeal disk largely punctured
c  Forewing: dense series of bristles as long as thickness of \( \text{CC} \) along the edge of the \( e \) vein basally to pterostigma
d  Forewing: apical veins of \( \text{CDM} \) and \( \text{CD II} \) tubular even though less thick than all the other veins
e  Hind tibial spurs spatula-like with stongly enlarged apical third (Fig. 28A)
f  Long bristles on the hindtarsomerus arranged in a weel distinct row (as it happens in Macromeria)
g  Microreticulation on 6th tergum larger and more impressed, evident at \( \times 10 \) magnifications too lasiotera nov.sp.

aa Clypeal disk with large smooth and hairless areas
bb \( \text{N}_1 \) and propodeal disk largely smooth
cc Forewing without bristles along the edge of the \( e \) vein
dd Apical veins of the forewings (\( \text{CDM} \) and \( \text{CD II} \)) nebulous
e e Hind tibial spur with only slightly enlarged apical third (Fig. 44)
f f Scattered long bristles on the hindtarsomerus, not arranged in a weel distinct rows
gg Microreticulation on 6th tergum fine and well detectable only at about \( \times 30 \) magnifications.................................................................7

7

a  Ventral \( \text{Es}_2 \) with large smooth area near \( \text{LaSt}_2 \).
b  \( \text{LaSt}_2 \) completely puncture-less........................................... limata (SMITH 1855)
aa Ventral Es$_2$ with regularly packed $p$. near Last$_2$, without any smooth area.

bb Last$_2$ with aevident clusters and stripes of $p$. on LaSt$_2$.................................8

8

a Declivitous surface of N$_1$ between disk and collar smooth and shining
b Metasoma completely bright ferruginous, petiole included, nowhere brown shades

................................................................. bonaespei (TURNER 1926)

aa Declivitous surface of N$_1$ between disk and collar completely covered by shallow $p$
bb Metasoma ferruginous to ferruginous-brown; the petiole and more or less extended
shades at least on the first metamerus are brown ............................................................9

9

a Vertex of head rounded and temples very narrow in frontal surface
b Palpi straw-coloured
c Pam: basal five elements almost isometric
d N$_1$ completely ferruginous. Metasoma ferruginous either with brown shades on the
first two-three metameri either with the basal three metameri completely brown

................................................................. sublevis (TURNER 1908)

aa Vertex of head subrectilinear and large temples in frontal surface
bb Palpi brownish
cc Pam: basal element just a bit less than twice longer than 4$^\text{th}$ and 5$^\text{th}$ elements
dd N$_1$ black/dark brown. Metasoma either completely ferruginous-brown with brown
shades either mostly light brown .................................................................deiandra nov.sp.

10

a Clypeal disk: either the whole or most part of ventral lamella well receding backwards
from the plane of the disk in ventral aspect (Fig. 47)
b Upper sub-tooth of the inner lobe of the mandible strongly bulging in frontal aspect
(Fig. 46)
c Labrum ventral surface: the waved row of $p$ bearing long bristles strongly bent, its
distance from posterior edge medially more than twice than laterally (Fig. 49)
d More often than not medium to large species (the largest ones within the genus) from
11 to 21 mm. Only one taxon less than 10 mm .........................................................11

aa Clypeal disk: either the whole either most part of of lamella complanar to the
remainder of disk in ventral aspect (Fig. 66)
bb Upper sub-tooth of the inner lobe of the mandible weakly bulging
cc Labrum ventral surface: the waved row of $p$ with long bristles holds throughout about
the same distance from the posterior edge (Fig. 66A)
dd Small to medium sized up till 12 mm..............................................................................17

11

a Very large lamella on the ventral clypeal border, as wide as ¾ its total width
b Propodeal disk strongly wrinkled and sculptured throughout, without any smooth area

................................................................. cruenta (TURNER 1916)

aa Central lamella of the clypeus no longer than 3/5 its total width
bb Propodeal disk with more or less extended smooth polished areas .................................12

12

a Dorsal area of propodeal disk almost completely smooth, without $p$ and with weak
lateral wrists; median furrow either absent either vestigial ....................... namachorites nov.sp.
aa Dorsal area of propodeal disk broadly $p$ and more impressed wrinkles; median furrow
long and well impressed ........................................................................................................13
13

a In frontal aspect, clypeal lamella large and narrow, not protruding under the line connoting the ventral edges of lateral areas. Propodeal disk with smooth shining subtriangular areas along the deep median furrow, strongly wrinkled laterally and posteriorly .................................................. *pallidipes* (TURNER 1916)

aa In frontal aspect, clypeal lamella higher, well protruding under the line connoting the ventral edges of lateral areas. Propodeal disk with larger, irregular smooth areas and less impressed median furrow and wrinkles. Patches and size variable ........................................ 14

14

a Body brown to dark brown without any ferruginous colour .................................................. *umbratica* (TURNER 1912)

aa Head and/or metasoma with more or less extensively bright ferruginous areas and shadings .......................................................... 15

15

a Head always almost completely bright ferruginous and metasoma black or dark brown. Great size, up to 21 mm .................................................. *rufifrons* (FABRICIUS 1793)

aa Head brown/dark brown, with ferruginous shadings at the most. Metasoma brown to ferruginous .................................................. 16

16

a Head and mesosoma dark brown, metasoma mostly ferruginous with brown shades; small size (∼ 8 mm) .................................................. *basutorum* (TURNER 1913)

b Body brown to dark brown with ferruginous two apical metameri and shadings on the sternum. Medium sized: 11/13 mm .................................................. *erythraea* nov.sp. Head dark brown, sometimes with ferruginous shadings; metasoma either completely ferruginous either with basal brown metameri. Great size, 13-18 mm .......................... *fusiformis* (DEGEER 1778)

17

a Stigma situated before one/fifth from the base of the forewing. Wings very short; forewing deeply bilobed and a just a bit longer than mesosoma, like in *Mertia geniculata*

b 2nd dorsal tergum with a broad, white, transverse band ............... *neavei* (TURNER 1911)

aa Stigma situated well beyond 1/5th the forewing. Wings as long as or longer than head and mesosoma jointly

bb 2nd tergum without transversal band, with only two lateral spot at most ......... 18

18

a Wings as long as or just a bit longer than aggregate length of both head and mesosoma in dorsal aspect .................................................. 19

aa Wings as long as head, mesosoma and 1st tergum at least ........................................ 20

19

a Apical stripe of Tsa thickened, with a gradulus dividing it from the remainder of surface

b Two lateral crests parallel to PoG, originating from the hypostomal carina and getting the eOc

c 2nd CSM absent .................................................. *perornata* (TURNER 1908)

aa Even surface of Tsa

bb No crests along PoG

cc 2nd CSM present .................................................. *quadrata* (TURNER 1913)
20

a The p bearing strong bristles on the dorsal surface of the scape stop just near the apex of the element; the distance of their end from the apex is less than half the length of 1st flagellomerus ...........................................................................................................

aa The p bearing strong bristles on the dorsal surface of the scape stop far off from the apex of the element with a distance from it as long as either just a bit less than length of 1st flagellomerus..........................................................................................................

21

a Metasoma with white patches on two terga at least
b Lateral ocelli very near vertex in frontal aspect, their distance from vertex far less than distance from each other
c Brown black body with only last two metamers ferruginous-brown Madagascar .........................................................................................................................luteipes BOI BARTALUCCI 2005

aa Metasoma without any white patches
bb Distance of lateral ocelli from vertex as long as their distance
cc Black to dark brown body with extended ferruginous patterns South Africa ........................................................................................................................................

22

a Mesosoma a bit less or as wide as 2nd metamer in dorsal aspect
b Metasoma glazed and bright ferruginous, with petiole and 1st sternum almost completely black-brown..............................................................rufinodis (TURNER 1910)

aa Mesosoma clearly wider than 2nd metamer in dorsal aspect: their relative ratio about 1.15
bb Metasoma light brown to ferruginous brown with darker basal two metamers....................

c Stenogastra nov.sp.

23

a Head strongly transversal in frontal aspect: ratio LA/A ~ 1.25.
b Metasoma, petiole included, completely bright ferruginous without any white patches
c 2nd tergum with gradulus greatly arched. Ratio LA/Am of postgradular surface in dorsal aspect about 4 .................................................................diapyrogastra nov.sp.

aa Head less transversal in frontal aspect: ratio LA/A ~ 1.15
bb Metasoma with brown shadows on 1st sternum at least. Large white patches on 1st to 5th terga with two small ones on 3rd sternum too. Large size: 14 mm
cc 2nd tergum with gradulus less arched, the ratio LA/Am of its postgradular surface in dorsal surface less than 3..........................................................multipicta (TURNER 1913)

24

a Glossa without a detectable notch apically (Fig. 11)
b Posterior lingual plate elliptic, with main axis less than twice the minor one
c Foretibial spur with velum narrower than trunk, with a waving edge and a short apical tooth; velum without defined combed edge(Fig. 14)
d 7th tergum without basal gradulus.................................................................oinodes nov.sp.

aa Glossa notched apically (well detectable in ventral aspect), less stressed in rufinodis and luteipes
bb Posterior lingual plate elongated with main axis more than twice the minor one
cc Foretibial spur with velum larger than trunk, with a straight edge and longer prominent apical tooth; velum with a large combed edge (Fig. 88A)

dd 7th tergum with basal gradulus (rufinodis, micruroides, pulchella, masaica,vonizongo, luteipes and gradilis lack it too; rufonigra lacks gradulus on 6th tergum too).................25
25

a N₁ in dorsal aspect with an elongated habitus. Its LAₐ just a bit greater than A₁ (~ 1.03 to 1.15)

b Ventral metasternum (St₃) stout, without prominent sharp apophysis (only bonaespei has state ββ)

c Gonostylus stout, strongly chitinised and pigmented

d Aedeagus long with a tapering tip and prominent lateral keel. In lateral aspect its tip gets the tip of gonostylus

e Digitus stout, its basal third mostly covered by the large extension of the volsellar cuspis in lateral inner aspect

Group of limata

26

aa N₁ in dorsal aspect clearly transversal. Its LAₐ greater than A₁ (more often ~ 1.35 or more)

bb Ventral metasternum normally with a couple of divergent sharp apophysis

cc Gonostylus more slender, normally weakly chitinised and pigmented

dd Aedeagus short with a semiglobular tip and without prominent lateral keeel. In lateral aspect its tip stands well underneath the tip of gonostylus

ee Digitus slender, almost completely exposed in lateral inner aspect

27

a Ratio LA/Aₘ of 2ₐ th tergum in dorsal aspect about 2.9

b Ventral border of dististylus without semicircular hollow

c Digitus with a rounded tip

limata SMITH 1855

aa Ratio LA/Aₘ of 2ₐ th tergum in dorsal aspect no more than 2

bb Ventral border of dististylus with a large semicircular hollow

cc Digitus with a tapering tip

28

a Stripe of sensilla trichoidea extending on half the thickness of the flagellomeri

b N₁ with an abrupt strangling forward in dorsal aspect

c Gonostylus with a protuberance just above the hollow .......... bonaespei (TURNER 1926)

aa Stripe of sensilla trichoidea extending on 4/5 the thickness of the flagellomeri

bb N₁ evenly narrowing forward in dorsal aspect

cc Gonostylus without any protuberance just above the hollow .......... sublevis (TURNER 1908)

29

a Stripe of sensilla trichoidea extending only on half the thickness of the flagellomeri

b 3ₐ to 6₁ th sterna with a large transversal furrow extended laterally where it forms a sort of hollow delimited by a strong rib parallel to laterotergal border.

c Dististylus with subparallel border in lateral aspect, not regularly tapering to the tip. (Fig. 35).................................................................................................... lasiotera nov.sp.

aa Stripe of sensilla trichoidea extending on more than half the thickness of the flagellomeri

bb Sterna with only a shallow transversal furrow and without lateral ribs

cc Dististylus regularly tapering to the tip

30
30

a  Stripe of sensilla trichoidea extending on 4/5 the thickness of the flagellomeri
b  $N_1$ with strongly arched posterior border. Ratio $A_1/A_m \sim 1.75$

c  Ratio $L_y/A_m$ of 2nd tergum less than 2 in dorsal aspect
d  Digitus subtriangular with tapering tip................................. *trachelopsila* nov.sp.
aa Stripe of sensilla trichoidea extending on the whole of the thickness of the flagellomeri
bb $N_1$ with slightly arched posterior border in dorsal aspect. Ratio $A_1/A_m \sim 1.25$
cc Ratio $L_y/A_m$ of 2nd tergum more than 2 in dorsal aspect
dd Digitus with rounded tip.................................................. *cingulata* (GERSTAECKER1857)

31

a  Scape surface roughly rounded without either any longitudinal costula (with only a very blunt angle at most) either a distinct flattened fore surface
b  Hind coxa with simply rounded inner ventral edge, without any supplementary longitudinal lamellar keel
c  7th Tergum without gradulus along its subbasal border
d  Metasoma more or less extensively reddened, but in *luteipes*.......................... 32
aa Scape with three longitudinal "costulae" (keels) (in *discontinua* almost laminated keel) and well distinct flattened fore surface.
bb Hind coxa with a supplementary longitudinal lamellar keel along its inner ventral edge
cc 7th Tergum with well expressed gradulus at its base
dd Metasoma without any reddening areas......................................................... 38

32

a  Volsella with evident prominent processes at the base of the bristles on its inner surface
  Madagascar & Kenya ......................................................................................... 33
aa Volsella without evident processes at the base of the bristles on its inner surface........ 35

33

a  Mesonotum ($Sc_1$) with a steep escarpment along its exposed anterior border and just behind the apical border of $N_1$ ......................... *gradilis* BONI BARTALUCCI 2005
aa Mesonotum ($Sc_1$) without any sort of escarpment.................................. 34

34

aa Basic colour of metasoma completely darkened without any ferruginous shades; many strong processes on the volsella. Madagascar ..................*luteipes* BONI BARTALUCCI 2005
bb Metasoma more or less flushed with ferruginous; 1st tergum entirely ferruginous, 7th tergum dark brown with yellow lateral spots. Weak and sparse processes on the volsella. Head subtriangular in frontal aspect. $N_1$ with a well expressed anteroventral tooth. Anterior surface of $Es_2$ mostly smooth and shining, without any p. Fore surface of the mid femurs completely and regularly p. Kenya.................................*masaica* nov.sp.
cc 7th tergum completely ferruginous without yellow lateral spots; 1st tergum dark brown. Head rounded in frontal aspect, a little larger than high. $N_1$ without anteroventral tooth. Anterior surface of $Es_2$ completely covered by shallow p, with I among them a little more than their diameter. Fore surface of the mid femurs p. only near its base. Madagascar..............................................*vonizongo* KROMBEIN 1949

35

a  Ssa smooth and shining without any sort of hair.
b  Fore surface of mid femurs almost completely hairless without any p....................... 36
aa Ssa roughly sculptured with scattered hair.

bb Fore surface of mid femurs almost entirely covered by weak p and hair ......................37

36

a Base of hypostoma large, prominent and transparent. PoG very feebly expressed. Pam shorter (8/10) than stipe. Yellow preapical stripes on the metameri as high as half the height of the element, with subrectilinear fore profile. Height of digitus 1/3 the height of volsella; cuspis strongly produced, as high as digitus. Somaliland .................................micruroides BONI BARTALUCCI 2001

b Base of hypostoma very narrow, darkened and flat. PoG well expressed. Pam 1.2 times longer than stipe. Yellow preapical stripes on the metameri narrow with irregular fore profile. Height of digitus 1/4 the height of volsella; cuspis weakly prominent, much lower than digitus. Sahel .....................pulchella BONI BARTALUCCI 2001

37

a Head subtriangular in frontal aspect. Base of hypostoma darkened, large and prominent. PoG and genal suture very feebly expressed. Last flagellomeri clearly thicker than basal ones. Light spots on 1st tergum. 7th tergum with a notch larger than high with subacute tips in dorsal aspect. South Western Africa.................................................. rufinodis (TURNER 1910)

b Head rounded in frontal aspect. Base of hypostoma darkened, narrow and flat. PoG and genal suture well expressed. Last flagellomeri as thick as basal ones. No light spots on 1st tergum. 7th tergum with a notch higher than large with rounded tips in dorsal aspect. Zimbabwe .......................................................... rufonigra (BINGHAM 1911)

38

a Fore border of N1 without laminated keel, the surfaces of disk and pronotal plate form only a blunt rounded angle. Most of the surface of the basal hind tarsomeres without short approached hair, but only with scattered thin bristles longer than its diameter. Disk of 1st tergum strongly transversal: ratio LA/Am a bit less than 4 .......................................................... anomalala nov.sp.

b Fore border of N1 always with a more or less extended laminated keeled. Basal hind tarsomeres entirely covered by all around its surface by approached hair shorter than its diameter. Disk of 1st tergum less transversal: ratio LA/Am about 2 ................29

39

a Ventral lamella of the clypeal disk entire without any notch.

b Temples straight, thicker or as thick as eyes in dorsal aspect............................................. discontinua (SCHULZ 1906)

aa Ventral lamella of the clypeal disk with a central notch, faible too

New species

*Meria oinodes* nov.sp.

Holotype $\varphi$ - Namibia = /WINDHOEK SE 2217 Ca 9.12 Nov 1973/ /H15022/ /NNIC/, NNMW
Paratype $\varphi$ - Namibia = (2) /WINDHOEK SE 2217 Ca 9.12 Nov 1973/ /H15022/ /NNIC/, NNMW
Paratype $\delta$ - Namibia = (7) /WINDHOEK SE 2217 Ca 9.12 Nov 1973/ /H15022/ /NNIC/, NMW

Female. Holotype. Figs 1-7. Measurements: body length = 9 mm; forewing length = 5mm.
The basic body color is reddish brown, darker in Sc₁, Sc₂, 1st sternum and areas behind preapical rows of points on terga, while most of mandibles, tibiae and tarsi, veins of the wings are light brown. Wings darkened. Patterns of p like in M. tripunctata, but on disk of the P which is mostly smooth with few p only along its lateral edges and no wrinkles. Pale yellow hair on the scape, where it strikingly contrasts with the integument of the head, mandible and clypeus, whitish hair elsewhere. Subhorizontal rough wrinkles on the posteroventral corner of lateral N₁. Well expressed median furrow on the dorsal P. 3rd CSM present. Gradulus well expressed on 2nd and very weak on 3rd tergum. Sul very short on 3rd and 4th terga. Preapical rows of p on metameri strongly bent like in Poecilotiphia.

Male. Figs 8-17. Measurements: body length = 12 mm.

Black, brown and pale yellow. Wings hyaline.

Pale yellow: most of clypeus and mandible, tip of Tsa, small spot on apex of the scape, two lateral long spots along foreborder and subapical stripe on N₁, half tegula, spot on Es₂, apex of X₁ and X₂, apical femurs, most of tibiae, tarsi, narrow subapical stripe with irregular foreprofile on 1st to 6th terga and 2nd to 5th sterna. Brown: border of Tsa, base of hypostoma, tip of mandible, flagellum, veins of the wings, shadows on metasoma. The whole of ventral border of clypeus is semitransparent.

Base of hypostoma scarcely swollen and with well expressed PoG, its length ¼ length of FoO. Secu stripe about 1/3 flagellar surface. No laminted keel along the foreborder of the N₁ disk, which ends with a strong anteroventral tooth. Su₃ like a stitch; Em₃ mostly smooth; lateral P smooth but a small posterior area. Signum very long (as long as 2nd hindtarsomerus). Foerasureface of the mid femur is almost completely hairless. Velum of the fore tibial spur not combed. Very fine poligonal mR (visible only at ×80 magnification with single cell hardly detectable) on 1st tergal disk and apical half of 2nd to 6th sterna. Transversal microreticuloation visible at ×50 magnification on basal half of 2nd to 6th sterna. p are densely packed on clypeus, Tsa, lateral frons, lateral Sc₂, postscutellar area, lower and lateral disk of P; more scattered with large smooth areas on vertex, mid N₁ and Sc₂, Sc₁. Nowhere hair concealing underlying integument.

Variability: only little differences about size can be detected about specimens of both sexes.

Ecology: unknown.

Derivatio nominis: from the Greek οινώδης = coloured like wine, because of the vinous colour of the female.

Discussion. About females, the character states of the key and the disposition of bristles on the scape are the same as in Poecilotiphia; the states 1χ, 1δ, 1ε and 1φ have also the function to discriminate the genus Meriodes from Meria. The mandible, wings, and foretibial spur are the same as in Meria. About males, the characters given in the key are not as settled as in females. Two other taxa at least (M. rufinodis and M. luteipes) have character state very close to 24α and other eight (M. rufinodis, M. micruroides, M. pulchella, M. masaica, M. vonizongo, M. luteipes, M. gradilis, M. rufonigra) show the character 24δ. The absence of the combed edge on the fore tibial spur is a peculiarity which occurs elsewhere within the tribe only in Iswara WEstwood 1851 males; its outline is as the same as in Poecilotiphia CAMERON 1902 males. Flagellum, hair and genitalia are like in Meria. There could be sufficient grounds to group them under a new
subgeneric name, nevertheless we lack definitive and incontestable proof about their coupling; moreover its unicity together with the weakness about the distinctive character states of the males both advise to exclude a similar drastic action for the present. Therefore in default of more data the choice to maintain them within the ancient genus *Meria* has been made.

*Meria phainoprocta* nov.sp.

Holotype ♂ - *Namibia* = /Richtofen 126 WINDHOEK 22°14’S 17°45’E Nov 1978 preservative traps S.Low, M-L.Penrith/ /H44753/ /NNIC/, NNMW

Paratype ♂ - *Namibia* = (1) / Richtofen 126 WINDHOEK 22°14’S 17°45’E 1-28 Feb 1979 preservative traps S.Low, M-L.Penrith/ /H52152/ /NNIC/, NNMW

Female. Holotype. Figs 18-19. Measurements: body length = 9 mm; forewing length = 5 mm.

Black, brown and light ferruginous-brown. Forewing very poorly darkened. Brown: mid and hind coxae; basal four metameri with lighter shadows. Light ferruginous brown: ventral border of clypeus; most of mandibles (but dark brown tips); mandible condyles and base of hypostoma; antennae; semitransparent apical border of the N1 disk and tegulae; apex of coxae and the remainder of legs, spines included; LaSt2: veins and pterostigma; apical two metameri and 1st laterotergum; bristles on clypeal disk and scape. Hair of the remainder of the body and spurs are whitish. PoG semitransparent, poorly developed and swollen; cOc ventrally entire, unbroken. Multiple rows of densely packed small p along the fore border of N1 disk; lateral N1 with well produced rugulae on its postero-ventral corner. P disk with short median weak furrow and lateral wrinkles.

Variability. Paratype is 6.5 mm long.

Male. Unknown.

Derivatio nominis. From the combination of the Greek nouns φαεινόσ (shining) and προκτός (back).

*Meria dissimilis* nov.sp.

Holotype ♂ - *Namibia* = /Blinkoog Warmbad SE 2719 Ca 14-17 oct 1971/ /NNIC/, NNMW

Female. Holotype. Figs 20-22. Measurements: body length = 8.5 mm; forewing length = 5 mm.

Black, Brown and ferruginous. Wings darkened. Brown: most of clypeus, Tsa, antennae and mandibles, LaSt2, most of legs which are lightening progressively from femurs to tarsi, petiole. Apical border of N1 disk, tegulae, pterostigma and vein are semitransparent brown. Ferruginous is the whole of metasoma but petiole. Hypostoma strongly prominent upon the genal area, its base very swollen and breaking cOc which is not entire ventrally. PoG not expressed. Lateral N1 without wrinkles. Horizontal P disk largely p packed in transversal rows with roughly defined median furrow. LaSt2 mostly p lateral P smooth, wrinkled only along its upper third. The p of remainder of the body as in other *Meria*. Brown hair on head and mesosoma, lighter on metasoma. mR detectable at ×40 only on the frons and anterior N1 disk.
Note. It lacks 7 left and 2 right flagellomerei, left hind tibia and tarsus, 4 right hindtarsomerei.

Male. Unknown.

Derivatio nominis: the latin dissimilis means different (from the other taxa).

**Meria lasiotera nov.sp.**

Holotype ♂ - Namibia = /NAMIBIA Bogenfels Oct 93/ /NNIC/, NNMW

Female. Paratype. Figs 23-28. Measurements: body length = 9 mm; forewing length =6.5 mm.

Black, brown, light reddish-brown, whitish. Wings hyaline. Brown: mandibles; antennae; forefemurs; mid and hindcoxae (forecoxae are black). Light reddish-brown: ventral lamella of clypeus; remainder of legs; LaSt2; metasoma. Whitish: roughly defined lateral spots on 1st to 4th terga. Base of hypostoma swollen, semitransparent, breaking ventrally eOc. No median furrow on P disk. Ventral surface of the lobes of St3 neither flattened neither contiguous medially but severed by a distinct groove and with a distinct lateral blunt apex. Pterostigma without inner differentiated area. Apical veins of CPM and CDn vein tubular, not nebulous like in the other taxa. Numerous bristles along basal half of coastal vein of both fore and hind wings. Hindtibial spurs strongly enlarged apically, almost spoon like. Disposition of pits and bristles on the basal hindtarsomerus is as the same as in *Macromeria*. mR well detectable at ×50 on the head, mesosoma (but posterior mesopleurae, LaSt2, vertical and lateral P, legs), terga (but apical areas), 2nd and 3rd sterna. Apical area of 6th tergum with a reticulated sculpture well detectable at ×10 magnification too. Clypeus densely p throughout (but a small lateral area) with dense hispidous hair. Dense p (distance among them less than thier diameter), bearing long white hair, also on vertical (pronotal plate) and lateral areas of N1 disk, postscutellar area, Es1 and Es2 horizontal disk of P, ventral edge of hind tibia, apical fore surface of hind femur, 1st to 4th lateroterga. Weaker and a bit more sparse p, bearing shorter white hair, on LaSt3, 1st tergal disk and lateral areas before preapical row of p on 2nd to 5th terga and apical half of 2nd and 3rd sterna (mostly smooth areas in other *Meria*).

Black, brown and yellow. Wings hyaline. Brown: tip of mandibles; mouthparts; dark portions of the legs but black X1. Yellow: most of mandibles; almost the whole of clypeus but a mid spot; two lateral spots along foreborder and one subapical stripe on N1 disk; tegulae; apical femurs, most of tibiae and the whole of tarsi; narrow apical stripe on 1st and three spots along apical borders of 2nd to 6th terga and 2nd to 5th sterna; two lateral spots on 7th tergum. Hypostoma semitransparent reddish and swollen; PoG short but distinct. Secu stripe ½ flagellar thickness. Ventral apophysis of metasternum blunt and only slightly protruding. 3rd to 6th sterna with a strong basal gradulus also extending laterally parallel to the laterotergal border. 7th sternum with only lateral graduli. Very densely packed p without any space among them and bearing long white hair covering the underlying integument on clypeus, frons, Tsa, temples, fore half and posteroventral corner of N1 disk, Es1, Es2, back and lateral areas of P.
Discussion. The male well belong to the group of limata because of genitalia. Well known from the other taxa of the group because of the dense long hair on the body, the graduli on the sterna and the gradulus on 7th tergum extended laterally to get the spiracular groove.

The female is distinct because of almost completely p clypeus, dense p bearing long bristles on hind legs and metameri, disposition of p on basal hind tarsomerus, tubular apical veins on the forewing, bristles on the coastal vein of the hind wing.

Ecology: unknown.

Derivatio nominis: from the Greek λασιώτερος = more woolly than.

**Meria deiandra nov.sp.**

Paratype ♂ - Namibia = (9) /Chulon, naribost 602 24°10’S 17°42’E MARIENTHAL DISTRICT 30 May-5June 1982 M-L.Penrith Preser traps, dune/ /NNIC/, NMW

Female. Holotype. Figs 37-44. Measurements: body length = 7.5 mm; forewing length = 4.5 mm.

Blackish, brown and light brown, whitish. Wings poorly darkened. Head and mesosoma are mostly blackish. Brown: most of the scape; tip of mandible; upper side of flagellum; most of legs; LaSt2; pterostigma; petiole and most of 1st tergum; shadows on other metameri. Clypeal lamella, mandible, tegula, veins, tarsi and the remainder of metasoma are light brown. Whitish: lateral spots on 2nd and 3rd terga; hair; spur; spines. Very short median furrow on the propodeal disk which show wrinkled lateral edges. Base of hypostoma semitransparent and slightly swollen; cOc unbroken ventrally even though weakened at the base of hypostoma. Densely packed p on ventral es2 without pitless areas near LaSt2 which show a stripe of p along inner border. St3 largely p. Poligonal mR detectable at ×50 throughout but areas on Es2, Em3, lateral P and legs. Transversal very fine mR on 1st to 5th metameri, longitudinal and greater on 6th tergum.

Variability. Paratypes vary in size from 6 to 9 mm and in tonality of the dark colour of head and mesosoma.

Ecology: unknown.

Male: unknown.

Derivatio nominis. From the Greek δεῖ (it lacks) and ανδρ- (root of ανήρ, ανδρός = male).

**Meria namachorites nov.sp.**

Holotype ♀ - Namibia = /Chulon, Narib Ost 602 24°10’S 17°42’E MARIENTHAL DISTRICT 30 May-5July 1982 M-L.Penrith Preser traps, dune/ /NNIC/, NNMW

Paratype ♀ - Namibia = /WINDHOEK SE 2217 Ca 22-24 Nov 1973/ /H75255/ /NNIC/, NMW

Paratype ♂ - Namibia = /Noachabeb 97 KEETMANSHOP SE 2718 Ad/Bc 22-28 Apr 1972/

Female. Holotype. Figs 45-49. Measurements: body length = 12 mm; forewing length = 7 mm.

Dark brown, brown and light brown, ferruginous, white. Forewing darkened, hindwing lighter. Most of the head and mesosoma are dark brown. Brown: part of mandible and
scape; all the legs but tarsi; LaSt2; pterostigma; petiole; 1st sternum; most of 1st tergum; large areas before white spots on 2nd tergum; irregular shadows on the remainder of metameri. Light brown: flagellum; ventral area of clypeal disk; most of mandible; palpi; tarsi; veins. Ferruginous: small areas on frons and vertex, most of metasoma.

White: lateral spots on 2nd and 3rd terga.

Base of hypostoma swollen and transparent, cOc broadly interrupted. Disk of N1 as mostly smooth as its lateral areas which have not wrinkled areas. Sub horizontal propodeal disk without median furrow, with fine wrinkles along its lateral edges; subvertical disk and upper fourth of lateral areas also wrinkled. Hindtibial spurs just a bit larger than in other congeneric taxa. Hair whitish throughout, p like in M. tripunctata. in most of the body.

Male. Figs 50-55. Measurements: body length = 14.5 mm.

Black, brown, yellow. Brown: ventral edge of clypeus; palpi; mandible tip; scape partially; hypostomal base; apex of coxae and dark portions of legs; apex of 7th metamerus and 8th sternum (anal hook). Yellow: almost all the clypeal disk; most of mandible; two large lateral spots along the fore border and a large subapical stripe on N1; small spot on Es2; apex of LaSt2; humeral plate and tegula; base of coastal vein; spot on all the coxae; ventral and apical femurs; almost completely tibiae; tarsi; large apical stripe with waving fore edge on 1st and 6th terga, 2nd, 5th and 6th sterna; large apical stripe with entire fore edge enlarging sideward on 2nd to 5th terga, 3rd and 4th sterna; three spots on 7th tergum.

Large Secu stripe, covering all the visible thickness of the flagellar elements; blunt keel, broken medially, along the fore border of N1 disk; fore surface of mid femur smooth and hairless; strong laminated longitudinal keel along inner ventral edge of X3; Sul well expressed only on 1st to 5th terga, vestigial on 6th one; sterna with a broad submedian transversal impression. Hair and p as in M. tripunctata.

Note. The female is clearly known from closer taxa by the absence of any trace of median furrow on the propodeal disk. The male has no very distinctive character states and can be identified through a combinations of characters given in the key. Their coupling here proposed is purely unwarranted.

Variability: the female paratype is smaller (11mm), has more extended brown areas on 1st and 2nd terga and lack ferruginous shadings on the head.

Ecology: unknown.

Derivatio nominis: from the name of the region, Nama, and the greek χωρίτης = dweller.

**Meria erythraea** nov.sp.

Holotype ♂ - Erythraea =/Eritrea (Asmara) 30.VI.1950 leg. S.Mochi/, MZUF
Paratype ♀ - Erythraea = (2) /Eritrea (Asmara) 30.VI.1950 leg. S.Mochi/, MZUF
Paratype ♂ - Erythraea = (2) /Asmara ETHIOPIA 7600' 18-20.I.62 S.M.Clark/, MZUF; (2)/Eritrea (Asmara) 30.VI.1950 leg. S.Mochi/, MZUF; (1) /Eritrea Asmara Bet Gerghis 29.IV.1950/, MZUF

Male. Holotype. Figs 56-61. Measurements: body length = 15 mm; forewing length = 10 mm.

Black, brown, yellow. Wings hyaline. Brown: tip of mandible; veins; legs but light areas. Yellow: irregular spots on clypeal disk; base of mandible; two lateral spots along the fore
border and one preapical stripe on N1 disk; subtriangular spot on Es2; humeral plate, basal coastal vein, most of tegula; small spots on X1 and X2, ventral and apical femurs, upper tibiae, tarsi; apical stripe with irregular fore edge enclosing laterally a small dark brown area on 1st to 4th terga and with simply indented fore edge on 5th, 6th terga, 3rd to 6th sterna; two lateral and one central spots on 7th tergum; three apical spots on 2nd sternum. cOc not broken by hypostomal basis. PoG short but clearly expressed. Hypostomal basis and PoG area swollen. Secu stripe covering half the thickness of flagellomeri. X3 with a longitudinal laminated keel along inner edge. 3rd to 6th sterna with a median transversal deep groove, severing an almost flat anterior and a swollen less impunctate posterior surfaces. 7th tergum with lobes not complanar, strongly bent both in lateral and back aspect. Quite dense white hair on lower frons, clypeus, genae, lateral N1, Sc2, Es2; P, lateral 1st sternum, 1st tergum. Sparse hair elsewhere. Digitus without any bristles.

Female. Figs 62-64. Measurements: body length = 11 mm; forewing length = 5 mm.

Dark brown, brown and light brown, ivory white. Wings darkened, hindwing lighter. Head and mesosoma more or less dark brown. Ventral mesosoma, legs and partially metasoma brown. Light brown are antennae, mandibles, Tsa, apical 4th, all 5th and 6th terga. Ivory white: two large lateral spots on 2nd and 3rd terga. cOc broken by the swollen semi transparent base of hypostoma. Lamella of clypeus strongly arched in ventral aspect with forwarding sides. Propodeal disk with median furrow and only few p along its lateral edges, without any wrinkle. 2nd petiolated CSM present.

Note. The specimens have been kindly given by W. Borsato (Venezia).

Ecology: unknown.

Derivatio nominis. From the area of provenance.

_Meria stenogastra_ nov.sp.

Female. Holotype. Figs 65-67. Measurements: body length = 8 mm; forewing length = 4.5 mm.

Black, brown, ferruginous brown. Wings slightly darkened. Brown: mandible; flagellum; legs but X1; LaSt2; pterostigma; 1st tergum but petiole which is almost black; most of 2nd tergum; 1st sternum. Veins and tarsi are light brown. Ferruginous brown: scape and the remainder of metasoma. Punctuated area with long bristles on the scape getting its apex. Hypostomal basis semitransparent and only slightly swollen; it does not break the cOc which is complete. Lateral N1 disk with strong short wrinkles on its posteroventral corner. Fine wrinkles on the sides of propodeal disk. Hair of the scape, clypeus and mandibles is light brown. Hair of the remainder of the body whitish like spurs and spines. p like the standard of the genus.
Note. Well identified by the colour patterns and the narrowness of metameri.

Male. Unknown.

Derivatio nominis. From the Greek στηνος = narrow and γαστηρ = abdomen.

**Meria diapyrogastra nov.sp.**

Female. Holotype. Figs 68-69. Measurements: body length = 9 mm; forewing length = 4.5 mm.

Black, brown, bright ferruginous. Wings light yellow. Brown: clypeus, Tsa, antennae, mandibles. Bright ferruginous are veins and pterostigma, LaSt2, legs but coxae, the whole of metasoma. Light brownish spurs, spines and hair throughout. Head strongly transversal in frontal aspect: ratio LA/A ~ 1.25. PoG not expressed, base of hypostoma semitransparent and swollen, breaking cOc which is not complete. Large semitransparent apical border of N1 disk. Fine wrinkles along sides of the horizontal area and strong waving wrinkles on the declivitous area of P. Gradulus of 2nd tergum well arched. p like the standard of the genus.

Male. Unknown.

Derivatio nominis. From the Greek διαπυρος = bright red and γαστηρ.

**Meria trachelopsila nov.sp.**

Holotype ♀ - Namibia = /Namibia WEST CAPRIVI PK. Kwanda river Susuwe 17°45’37S 23°20’55E 28.IX-02.X.1996 HH Kirk Spries Malaise traps dry woodland/ /NNIC/, NNMW

Male. Holotype. Figs 77-84. Measurements: body length = 12 mm; forewing length = 6 mm.

Black, brown, yellow. Wings hyaline. Brown: tip of mandible: flagellum; palpi; veins and pterostigma. Yellow: tip of Tsa; most of clypeal disk; external mandible; two lateral spots along foreborder and one subapical stripe on N1 disk; apex of LaSt2; tegulae; about half femurs, all tibiae and tarsi; apical stripe with entire for edge on 1st to 6th terga, apical stripe with anterior lateral indentations on 2nd to 6th sterna; median spot on 7th tergum. Base of hypostoma semitransparent and a bit swollen; cOc unbroken; ventral border of clypeus semitransparent; fore surface of mid femur mostly smooth and hairless; Em3 finely wrinkled; gradulus on 2nd to 7th terga; sul on 1st to 6th terga; narrow transversal median furrow on 2nd to 6th sterna, making a sort of gradulus before it; median longitudinal broad keel on the last third of 7th sternum. White hair denser on frons, N1 disk, Es2, never concealing the underlying integument.

Variability. There are only little variations about size and colour patterns in the paratypes.
Female. Paratype from Etosha NP. Measurements: body length = 7 mm.
It is very close to the female of *M. sublevis* from which it strongly differs because of the brown to light brown basic colour of the body. The coupling is purely indicative.
Note. The shape of genitalia reveals its membership to the *M. limata* group.
Female: unknown.
Ecology: unknown.

Derivatio nominis: from the Greek τράχηλος (= neck) and ψιλός (unarmed, bare) because of the absence of any keel on the pronotum.

*Meria leucospila* nov.sp.

Holotype ♂ - Namibia = /Namibia LÜDERITZ DISTRICT Obib waters 19-21.IX.1997 28°00’S 16°38’EE.Marais & Kirk-Spriggs malaise trap sample/, NNMW
Paratype ♂ - Namibia = (2) /Namibia LÜDERITZ DISTRICT Obib waters 19-21.IX.1997 28°00’S 16°38’EE.Marais & Kirk-Spriggs malaise trap sample/, NNMW; (1) /Namibia: LÜDERITZ Rooiberg 27°38’S 16°28’E 22-24.IX.1997 Kirk Spriggs & Marais malaise trap sample/ /NNIC/, NNMW

Male. Holotype. Figs 85-91A. Measurements: body length = 12.5 mm; forewing length = 6.5 mm.
Black, brown, white. Wings hyaline. Brown: Semitransparent basis of hypostoma; most of mandibles; most of the legs with lighter tarsi, tibiae and tip of femurs; lateroterga from 2nd to 7th terga; sterna; veins and pterostigma. White: two irregular spots on clypeal disk; two small stripes on each Tsa; base of mandibles; two very narrow stripes along fore border of N1 disk; apex of LaSt2; spot on fore and mid coxae; three small spots very close to each other on 1st tergum; three small spots along apical border on 2nd to 6th terga and sterna, their distance bigger than their size; two lateral spots on 7th tergum. Swollen hypostomal basis; cOc almost complete, worn out just near the middle of it; Secu stripe at least as wide as thickness of flagellomeri; lamellar keel along the fore border of N1 disk interrupted medially in two subrounded (in frontal aspect) portions wearing out toward anteroventral corner; Em3 and lateral P almost smooth and shining; upper third of fore surface of mid femur with dense very weak p and hair, lower two thirds smooth; strong longitudinal lamellar keel along the inner ventral edge of X5; well expressed graduli on 2nd to 7th terga; sul present on 1st to 6th terga; quite deep transversal median furrow on 2nd to 6th sterna extending laterally like it happens in *lasiotera* (Fig. 33); surface before it more densely p than surface behind it (a general pattern in the genus). p is denser on clypeus, lower frons, lateral N1, Es2, N3, posterior and lateral P, bearing long white hair which conceals the underlying integument. Tergal disks are bipunctate with microp becoming more scattered from 1st to 7th tergum.
Variability. Little variations in shape of colour patterns. Size varies from 12 to 14 mm.
Note. Very distinct by the dense hair, the shape of sterna, the bipunctate surface of terga and shape of genitalia.
Female: unknown.
Ecology: unknown.

Derivatio nominis: from the Greek words λευκός = white and σπίλον = spot.
Meria anomala nov.sp.
Holotype ♂ - Namibia = /15 km NE Sylvia hill Sc2514 Bb LÜDERITZ 16.16 Sept 1971/, NNMW
Male. Holotype. Figs 92-102. Measurements: body length = 14.5 mm; forewing length = 7 mm.
Black, brown, yellow. Wings hyaline. Brown: tip of mandible; veins and pterostigma; legs but yellow parts; narrow area along fore edge of the yellow bands on terga and sterna; apex of 8th sternum. Yellow: apex of Tsa; two large lateral spots along fore border and a large subapical stripe on N1 disk; a small spot on Es; apex of LaSt; inner tegula (with transparent remainder); ventral and apical femurs, dorsal tibiae, mid and hind tarsi; apical stripe with waving edge on 1st tergum, apical stripe encircling laterally brown spots on 2nd to 4th terga; apical stripe laterally indented on 5th and 6th terga, irregular spot on 7th tergum, three spots becoming smaller from 2nd to 6th sterna. cOc incomplete broadly broken by the swollen semitransparent hypostomal basis. Secu stripe broader than thickness of flagellomeri. Sensilla basiconica larger than in other taxa of the genus, their size about 2×10^-2 mm like in Macromeria. No laminated keel along the fore border of N1 disk. Em as smooth as anteroventral lateral P. Disk of P distinctly flattened posteriorly, subhorizontal and subvertical areas forming a 45° angle. St3 with sub conical ventral processes. Fore surface of mid femur completely smooth. Strong laminated keel along anterior (inner) ventral edge of X3. Basal hind tarsomerus without appressed hair on its postero-dorsal surface. Hollowed declivitous 1st tergum, well distinct from the strongly transversal upper disk. Graduli on 2nd to 7th terga. sul present from 1st to 6th terga.
Note. Well distinct taxon from the remainder of genus. Good autapomorphies are the great Sensilla basiconica, sub conical ventral processes of St3, the lacking of appressed hair on basal hind tarsomerus, hollowed 1st tergum, short petiole.
Female. Unknown.
Derivatio nominis. Because of its anomalies compared to the other taxa.

Meria dasymetopa nov.sp.
Holotype ♂ - South Africa = /CAP/ /capensis n.sp. Ss (blue) /C.ne Saussure/ /Tye/ (red), MHNG
Paratype ♂ - South Africa = /Hex river jan 9.84/ /C.ne Saussure/, MHNG
Male. Holotype. Figs 103-110. Measurements: body length = 15 mm; forewing length = 8 mm.
Black, brown, pale yellow. Wings hyaline. Brown: tip of mandible; legs but fore and mid coxae and yellow areas; lateroterga partially. Yellow: tip of Tsa; most of mandible and clypeus; two lateral spots along the fore border and a subapical stripe on N1 disk; most of tegula; tarsi, most of tibiae, ventral and apical femurs, large spot on coxae; Apical stripe with largely indented fore edge on 1st to 6th terga and 2nd to 6th sterna; two lateral spots on 7th tergum. Transparent ventral edge of clypeus. Hypostoma semitransparent brown, swollen but not breaking cOc which is complete. Secu stripe a bit larger than 2/3 thickness of flagellomeri. Em smooth. Mid femur fore surface smooth and hairless. Hind coxa with a strong supplementary longitudinal laminated keel on its inner (postero) ventral edge; its inner dorsal keel irregular and less raised. Densely set fine p on the lower
frons, Tsa, clypeus, most of N₁ disk and P, bearing long white hair which almost con-
ceals underlying integument. More scattered fine p elsewhere with long hair not concea-
ling integument. Declivitous subtriangular surface of 1ˢᵗ sternum with densely packed p
throughout.
The paratype does not show significant differences.
Female: unknown.
Ecology: unknown.
Derivatio nominis: from the Greek words δασύς = hairy and μέτωπον = frons, because of
the hairy frontal head.

**Meria masaica** nov.sp.
Holotype ♂ - **Kenya** = /KENYA Kilifi VI.87 Werner leg/, MZUF
Male. Holotype. Figs 111-118. Measurements: body length = 15 mm; forewing length =
8 mm.
Black, brown, yellow, ferruginous. Wings hyaline. Brown: most of vein; dark portions of
legs; some shadings on 2ⁿᵈ tergum;basal palpmeri (the remainder are straw coloured).
Pterostigma and apical veins are lighter. Yellow: most of clypeus and mandible; apical
spot on Tsa; two lateral stripe along fore border and one large subapical stripe on N₁
disk; most of tegula; large spot on es₂; most of LaSt₂; oblong spot on coxae, ventral
femurs, dorsal tibiae, tarsi; Narrow stripe on 1ˢᵗ tergum.; larger stripe with roughly
indented fore edge on 2ⁿᵈ to 6ᵗʰ terga; lateral rounded spots on 7ᵗʰ tergum and 2ⁿᵈ to 6ᵗʰ
sterna. Ferruginous: 1ˢᵗ metamerus but apex of petiole; basal third of 2ⁿᵈ sternum and
shadows on lateroterga. Hypostoma transparent and slightly swollen not breaking cOc
which is complete. Semitransparent ventral border of clypeal disk. Ssa with vertical
wrinkles. N₁ disk with laminated keel just near the anterodorsal corner and with an
anteroventral tooth. Gonostylus is as the same as in the group of rufinodis and volsella
shows subtriangular microprotuberances above the base of the bristles on its inner sur-
face (like in the madagascan taxa).
Female: unknown.
Ecology: unknown.
Derivatio nominis: from the name of the most famous kenian people.

**New combinations**

**Meria servillei** (GUÉRIN 1837) comb.nov.
Myzine servillei GUÉRIN 1837: 576 - Neotype here designated to ensure name’s proper and consist-
tent use: SouthAfrica = /S.B Myzine servillei Cap B.Sp./ /Spin/ /Peringuey Cap ?/ (blue)
/Type/ (red), MHNG.
Material: ♂ - South Africa = (1) /CAP/ /Servillei Guer Broch, Myz. p10/, MHNG.
Male. Neotype. Figs 70-76. Measurements: body length = 15 mm.
Here the very brief Guérin’s description: "Tête et antennes noires sans taches. Thorax
noir avec deux petites stries jaunes interrompues sur le prothorax. Ailes transparentes,
incolores; pattes fauves avec les cuisses noires; abdomen noir avec le bord fauve; le premier segment ayant une bande et les autres trois taches postérieures jaunes. Dessous sans taches, avec le bord postérieur des segment brunatre. Longueur, 16 millimètres. Du Cap”. The specimen here named neotype shows the following small differences from his description: mostly yellow clypeal disk, a small spot on E\textsubscript{s} and LaSt\textsubscript{2}, fore coxa, a spot on mid and hind coxae, lateral spots on 7\textsuperscript{th} tergum, yellowish narrow apical, laterally indented, stripes on 2\textsuperscript{nd} to 6\textsuperscript{th} sternum too. The most significative difference is the presence of the yellowish stripes on the sternum, since the other ones concern morphological particulars that Guérin regularly overlooked in the descriptions. The basic body colour of the head and mesosoma is black, of metasoma brown. The distal half of 2\textsuperscript{nd} to 6\textsuperscript{th} sternum is ferruginous brown, but the narrow area between indentation which is as brown as basal half of the metameri. PoG short but clearly expressed and quite swollen together with hypostomal basis. cOc complete. Secu stripe covering all the thickness of flagellomeri. Fore border of N\textsubscript{1} with a lamellar keel just on the mid and worn out laterally where it becomes blunt. Back half of E\textsubscript{m} finely wrinkled. Anteroventral corner of P roughly wrinkled. Fore (inner) surface of mid femur almost completely set with very weak p and hair. Longitudinal strong lamellar keel along inner ventral edge of X\textsubscript{3}. Gradulus on 2\textsuperscript{nd} to 6\textsuperscript{th} tergum. Gradulus on 7\textsuperscript{th} tergum irregular and worn out laterally. It lacks last three right and ten left flagellomeri.

The other specimen shows a continuous subapical stripe on N\textsubscript{1} disk and lacks seven right and three left flagellomeri.

Meria sublevis (TURNER 1908) comb.nov.

Myzine sublevis TURNER 1908: 500-501

New records

**Meria fusiformis** (DE GEER1778)

*Apis fusiformis* DE GEER 1778: 608

Examined specimens:

♀ - Namibia = (1) / Plateau 38 Luderitz SE2616Cb 4-5 Mar 1972 / NNIC, NNMW.

♂ - Namibia = (1) / Riverside 135 Bethanie SE2616Ca 23-26 Oct 1971 / NNIC, NNMW; (1) / Halali 19°02S 16°58'E Etosha Nat. Park 18/20 Jan 1987 E. Marais, J. Irish / NNIC, NNMW.

**Meria rufifrons** (FABRICIUS 1793)

*Larra rufifrons* FABRICIUS 1793

*Meria spinolae* WESTWOOD:

*Meria rufifrons*: JACOT GUILLARMOD (1961: 3-4, under *Myzine (Meira) violaceipennis* CAMERON 1905 as its synonym)

Examined specimens:

♂ - Zimbabwe = (1) / Lonely Mine Rhodesia H. Swale 22 IV 14 // Meria rufifrons (Fabr) J.C. Guillarmod det 1949 / BMNH. South Africa = (1) / Nr. Johannesburg Transvaal AJ Cholmley 1906-26 / see type Plesia continua Cam / Meria rufifrons (Fabr) J.C. Guillarmod det 1949 / BMNH

Note. I could not examine the type of *Plesia continua* CAMERON 1905 since I did not
succeed to obtain any loan from Albany Museum, nevertheless its synonymy with *rufifrons* is highly probable as already stated by Turner (1910).

**Meria limata Smith 1855**

*Meria limata* Smith 1855: 81 [Lectotype ♀, here designated to ensure name’s proper and consistent use: South Africa = /Int S. Africa/ /43 19/ (both rounded) /limata Sm. Type/ (autographic) /Type/ (rounded with outer red ring) /B.M.Type Hym. 15.1519/, BMNH !]

*Plesia transvaalensis* Cameron 1910: 119 [Lectotype ♂, here designated to ensure name’s proper and consistent use: South Africa = /Kransp19.12.06/ /Plesia transvaalensis Cam. Type/ (autographic) /Type Hym 1936 Plesia transvaalensis Cameron/ (red), TMP !]. **Syn.nov.**

**Examined specimens:**
♀ - South Africa = (2) /Transvaal/ /Meria limata ♀ Sm det 1949 J.C.Guillarmod/, TMP; (1) /Font ??? Capland Dr Brauns 15.1.06/ /Meria limata ♀ Smith det 1949 J.C.Guillarmod/, BMNH; (1) /South Hills Johannesburg S afr 7.11.64 H.N.Empey/ /M.limata Smith 1964 Det. H.N.Empey/ /A003200/, SAM.
♂ - South Africa = (2) /Transvaal/ /Meria limata ♂ Sm det 1949 J.C.Guillarmod/, TMP; (1) /South Hills Johannesburg S afr 7.11.64 H.N.Empey/ /M.limata Smith 1964 Det. H.N.Empey/ /A003200/, SAM.

Note. Southafrican students are the authority for the aforesaid synonymy, especially J.C.Guillarmod who determined as *M. limata* male specimens identical to the Cameron’s type, whose in all probability he took notice. The specimens determined by Empey, who certainly based himself on the Guillarmod’s determinations, were probably caught in copula.

**Conclusion**

A total of 37 species follows from this study. They are so distributed:

**Angola**: 1 = *M. discontinua*

**Botswana**: 5 = *M. discontinua, M. fusiformis, M. rufonigra, M. sublevis, M. umbratica*

**Ethiopia - Erythraea**: 2 = *M. cingulata, M. erythraea*

**Kenya**: 1 = *M. masaica*

**Madagascar**: 3 = *M. gradilis, M. luteipes, M. vonizongo*

**Mozambique**: 2 = *M. cingulata, M. limata*

**Namibia**: 14 = *M. anomala, M. deiandra, M. diapyrogastra, M. discontinua, M. fusiformis, M. hormopsila, M. lastotera, M. leucospila, M. namachorites, M. oinodes, M. phainoprocta, M. rufinodis, M. stenogastra, M. sublevis*
Sahel: 1 = *M. pulchella* (*Meria diplochora* has been placed arbitrarily within Palearctic fauna)

Somaliland: 1 = *M. micruroides*

South Africa: 19 = *M. basutorum*, *M. bonaespei*, *M. cingulata*, *M. cruenta*, *M. dasymetopa*, *M. discontinua*, *M. fusiformis*, *M. inconspicua*, *M. limata*, *M. multipicta*, *M. neavei*, *M. pallidipes*, *M. perornata*, *M. quadrata*, *M. rufifrons*, *M. rufinodis*, *M. rufonigra*, *M. servillei*, *M. sublevis*, *M. umbratica*

Zimbabwe: 2 = *M. rufifrons*, *M. basutorum*

Acknowledgments

The author is grateful for the loan of the material to M.A. Cochrane (Cape Town, SAM), B. Dombrowsky (Pretoria, TMP), Frank Koch (Berlin, MNHU), Ivan Löbl and Bernhard Merz (Genève, MHNG), Walter Borsato (Venezia, MSNV), Guido Pagliano (Torino, MRSNT), Walter Raineri (Genova, MSNG), Suzanne Ryder and Conrad Gillet (London, BMNH). Special thanks to Eugene Marais (Windhoek, NMNW) for the loan of material from Namibia which has formed the main framework of this publication.
