Keywords: *Brassicaceae*, *Cardamine amara* L., The Carpathians, Central Europe, *Cruciferae*, Pannonia, Taxonomy

Abstract: The results of a taxonomic study of *Cardamine amara* L. from the Carpathians and Pannonia are presented. Two subspecies, *Cardamine amara* L. subsp. *amara* and *C. amara* subsp. *opicii* (J. PRESL & C. PRESL) ČELAK., are shown to occur in the area studied. Full synonymy, descriptions, chromosome numbers, taxonomic history, distribution data, and ecological notes are provided.

INTRODUCTION

This paper is the second in a series presenting a taxonomic revision of the genus *Cardamine* in the Carpathians and Pannonia. It deals with two subspecies of *Cardamine amara* L.: *C. amara* L. subsp. *amara* and *C. amara* subsp. *opicii* (J. PRESL & C. PRESL) ČELAK. For an explanation of the materials used and arrangement of data see MARHOLD (1994).

Cardamine amara L.

The results of a multivariate morphometric study of *Cardamine amara* in the Carpathian and Sudeten Mts. (MARHOLD 1991, 1992) showed that two subspecies, *C. amara* subsp. *amara* and *C. amara* subsp. *opicii*, could be recognized in this area. Only diploid populations of this species were found to occur here. The presence of tetraploids, reported by HINDÁKOVÁ (1974) from the Velká Fatra Mts., has not been confirmed.

There are only diploid chromosome counts for this species from the area of Pannonia. However, recent studies (MARHOLD 1993, MARHOLD, unpubl.) of the tetraploid populations of *Cardamine amara* s.l. from the Austrian Alps indicate that some specimens of *C. amara* subsp. *amara* cited here for the Austrian part of Pannonia may belong to tetraploids. These populations may represent a new, as yet undescribed subspecies (see below), but they require further study. Morphological description of *C. amara* subsp. *amara* in this paper is based entirely on the diploid material.

Cardamine amara L. Sp. Pl.: 656, 1753.

Ind. loc.: "In Europae septentrionalis nemoribus". Lectotypus: (LINN, no. 835.17) (KHATRI 1989: 92).

Taxonomic history

RETZIUS (1779) recognized within Scandinavian populations of *Cardamine amara* two taxa based entirely on the nature of the indumentum, namely *Cardamine amara* var. *glabra* RETZ. and *C. amara* var. *hirsuta* RETZ. A similar classification can also be found in the works of other authors. The indumentum of *C. amara* is to a large extent variable and, as a consequence, any classification based solely on this character is unlikely to be natural (cf. LÖVKVIST 1957).

Morphological differences between plants from lower altitudes and those from the Sudeten Mts. were recognized, probably independently, by the Presl brothers (PRESL & PRESL 1819) and by WIMMER & GRABOWSKI (1829), and later also by KOCH (1835).

The description of *Cardamine opicii* in Flora Čechica (PRESL & PRESL 1819) is based mainly on the morphology of the cauline leaves. The character “fol[iis] ... stipulatis” in the description refers to very small leaflets near the leaf base. The description, however, does not provide reliable differentiating characters between *C. amara* and *C. opicii*, which has probably caused the misinterpretation of this taxon by later authors. PRESL & PRESL (1819) also demonstrated differences in the indumentum between plants of their *C. opicii*, dividing it into “ α Caule petiolisque hirsutis” and “ β iisdem [caule petiolisque] glabriusculis”. While the stem of *C. amara* subsp. *amara* is usually sparsely hairy at the base, that of *C. amara* subsp. *opicii* is either glabrous or densely hairy. Glabrous and densely hairy plants occur, however, within almost every population of this subspecies, and thus the nature of indumentum is here considered of no taxonomic importance.

WIMMER & GRABOWSKI (1829), when describing *C. amara* var. *umbrosa* WIMM. & GRAB. [an illegitimate name, due to the earlier validly published *C. amara* var. *umbrosa* (LEJ.) DC.], did not mention the occurrence of glabrous plants, although they did correctly stress the importance of a simple stem when distinguishing this taxon from *C. amara* var. *amara*. KOCH (1835) mentioned the importance of the difference in number of leaflets between *C. amara* var. *amara* and his *C. amara* var. *subalpina*. A detailed study of the morphological characters of *C. amara* in the Sudeten Mts. was published by UECHTRITZ (1872). He presented a taxon, corresponding with the PRESLS' *Cardamine opicii*, at the level of the geographic race as *C. amara* B. *multijuga* R. UECHTR. According to Article 35.2 of the Code (GREUTER et al. 1994) it is inoperative in questions of priority.

Populations of *Cardamine amara* s.l. in the Eastern Alps were studied by HABELER (1963). Her results were influenced by a misunderstanding of the name *C. opicii* which she tried to apply to the populations from the Alps. She concluded that *C. amara* is a highly variable species without any possibility of infraspecific classification. This influenced the authors of Flora der Schweiz (HESS et al. 1970), and the latest edition of Hegi's Illustrierte Flora von Mitteleuropa (SCHULZE-MOTEL 1986). However, studies of the present author indicate that while diploid populations from the Alps belong to *Cardamine amara* subsp. *amara*, tetraploids occurring in this area may represent a different, as yet undescribed taxon (MARHOLD 1993).

Brief description

Perennial herb, 10-60 cm tall. Rhizome long, prostrate, 1-13 mm wide. Stem erect, sometimes flexuous, simple or branched above, slightly sulcate, glabrous or sparsely to densely hairy. Leaves not in a rosette; cauline leaves 2-53, with 2-11 pairs of lateral leaflets; leaflets sessile or shortly petiolulate, oblong to suborbiculate, almost entire, or lobate, crenate, or sharply crenate, sometimes ciliate, glabrous or with appressed hairs on upper surface.

Inflorescence racemose, simple or compound, with 2-40 flowers in the main inflorescence; sepals ovate, 2.8-5.2 mm long, glabrous, margin membranous; petals white (rarely, especially in buds, reddish-violet), obovate to oblanceolate, 5.7-10.2 mm long \times 2.6-6.2 mm wide, with short claw, apex truncate to emarginate; stamens 6, indistinctly tetrodynamous, filaments of longer stamens 3.3-7.3 mm, anthers reddish-violet before anthesis; stigma not conspicuous. Pedicels erect-patent or patent, siliquae divergent at the same angle as pedicels or erect, 20-40 mm long \times 1.0-1.5 (-2.0) mm wide.

Key to the subspecies of *Cardamine amara*

1	Stem branched, with lateral inflorescences	subsp. <i>amara</i>
1*	Stem simple, without lateral inflorescences	2
2	Stem densely hairy	subsp. <i>opicii</i>
2*	Stem glabrous or sparsely hairy	3
3	Stem leaves (2-) 3-14 (-24), not congested beneath inflorescence; lower stem leaves with 2-6 (-7) pairs of lateral leaflets	subsp. <i>amara</i>
3*	Stem leaves (10-) 13-46 (-53), congested beneath inflorescence; lower stem leaves with (4-) 5-9 (-11) pairs of lateral leaflets	subsp. <i>opicii</i>

Brief description

Rhizome thin. Stem stiff, erect, sometimes flexuose, usually only sparsely hairy at base, simple or branched above, 1-6 mm wide at base. Cauline leaves (2-) 3-14 (-24), thin, not congested beneath inflorescence, with 2-6 (-7) pairs of lateral leaflets. Inflorescence simple or compound, with 2-40 flowers in the main inflorescence. Sepals (2.8-) 2.9-4.2 (-4.5) mm, petals (6.1-) 6.8-9.7 (-10.2) mm long and (2.9-) 3.5-5.7 (-6.2) mm wide, filaments of longer stamens (3.8-) 4.7-6.9 (-7.3) mm, pedicels glabrous.

Flowering: April - May.

$2n = 16$

General distribution

Cardamine amara subsp. *amara* occurs throughout most of Europe, except in the North. In the South it extends as far as Spain, central Italy, and southern Romania, while in the east as far as western Siberia.

Distribution in the Carpathians and Pannonia

This subspecies is widespread in the Carpathians, except high altitudes of the West Carpathians, where it occurs only exceptionally. It is more common in higher altitudes of the South Carpathians. In Pannonia it is far rarer, and for some parts of this area it is probably absent.

Ecology, phytosociology

Cardamine amara subsp. *amara* occurs in forest spring communities, alder forests, ridges, wet meadows and other places with standing or slow flowing water, and prefers acid or almost neutral soils of the gleyed type. It belongs to the group of characteristic taxa of the suballiance *Alnenion glutinoso-incanae* OBERD. 1953 (which includes, for example, the association *Cardamino-Alnetum incanae* ŠOMŠÁK 1961) and alliance *Cardaminion amarae* MAAS 1959 (with the associations *Cardaminetum amarae* (BR.- BL. in BR.-BL. et al. 1926) MAAS 1959 and *Cardamino-Chrysosplenietum alternifolii* MAAS 1959). It also occurs in communities of the alliances *Alnion glutinosae* MALCUTT 1929, *Salicion cinereae* TH. MÜLLER & GÖRS ex PASS. 1961, *Salicion eleagni* MOOR 1958, *Salicion triandrae* TH. MÜLLER & GÖRS 1958, *Salicion albae* (OBERD. 1933) TH. MÜLLER & GÖRS 1958, *Caricion rostratae* BAL.-TUL. 1963, and *Caricion davallianae* KLIKA 1934.

General distribution

Cardamine amara subsp. *opicii* occurs in the Sudeten Mts., namely the Krkonoše Mts. (= Karkonosze Mts.), Mt. Králický Sněžník (= Masyw Śnieżnika Mts.), Hrubý Jeseník Mts., and also probably the Orlické hory Mts. (for a detailed distribution see HROUDA & MARHOLD 1993). It is widespread in the higher mountains of the East and West Carpathians. In the South Carpathians it is rather rare. This subspecies probably does not occur in the Alps. The data concerning its occurrence in that area most likely refer to tetraploid populations of *C. amara*.

Romania

Districts Maramureş, Bistriţa-Năsăud, Mureş [?], Harghita [?], Braşov [?], Argeş [?], Sibiu, Hunedoara, Caraş-Severin (in the mountains of Maramureşului, Rodnei, Căliman, Făgăraşului, Retezatului, Țarcului).

Minimum altitude: Veľká Fatra, Ľubochnianska dolina, above the Raková forester's house, 850-900 m, 1985, MARHOLD (SAV). Maximum altitude: Vysoké Tatry, Päť Spišských plies, 2013 m, 1890, 1907, SIMONKAI (BP); Vysoké Tatry, NE of the Hincove pleso, ca. 2000 m, 1955, STANĚK (BRNM).

Ecology and phytosociology

Cardamine amara subsp. *opicii* occurs in springs, on stream banks, and wet rock faces in the upper montane, subalpine, and alpine belts, on acid or almost neutral soils of the gleyed type. It belongs to the characteristic taxa combination of the associations *Brachythecio rivularis*-*Cardaminetum opizii* (KRAJINA 1933) HADAČ 1983 and *Calthetum laetae* KRAJINA 1933 of the alliance *Cratoneuro filicini-Calthion laetae* HADAČ 1983. It also occurs in other associations of this alliance [e.g. *Caltho-Dicranelletum squarrosoae* HADAČ 1956 and *Arabido alpinae-Petasitetum kablikiani* (HADAČ in HADAČ et al. 1969) HADAČ 1983], and in communities of the alliance *Adenostyliion* BR.-BL. 1926 (e.g. *Aconitetum firmi* KRAJINA 1933).

Acknowledgments: I would like to thank the directors and curators of the herbaria who allowed me to study material, and Prof. A. Jasiewicz and Prof. J. Mądalski who kindly loaned their personal herbaria. I am also grateful to Drs C. Drăgulescu, A. Kahalo, L. Hrouda, J. J. Wójcicki, and M. Zagulskij for their help in the field, to Doc. Dr V. Feráková, CSc. for valuable comments, and to Mrs. K. Cigánová for providing the illustrations. This work was supported by the Grant Agency for Science, Bratislava, Slovakia (Grant No. 2/41/92) and by the Ministry for Science and Research, Vienna, Austria, through the East-West Programme of the Austrian Academy of Sciences (Project No. OWP 58), which is gratefully acknowledged.
